Reflect : Record.

VOLUME LX.—1918.

PUBLISHED BY

THE S. S. WHITE DENTAL MANUFACTURING CO.

211 SOUTH TWELFTH STREET, PHILADELPHIA.

1918.

CONTENTS OF VOLUME LX.

1918.

First pages of monthly issues:

| PAGE | PAGE | PAGE | PAGE |
|--------------------|-----------------|---------------------|---------------------|
| JANUARY 1 | APRIL 287 | JULY 555 | OCTOBER 857 |
| FEBRUARY 101 | MAY 381 | AUGUST 659 | NOVEMBER 963 |
| MARCH 197 | JUNE 473 | SEPTEMBER 759 | DECEMBER 1071 |

ORIGINAL COMMUNICATIONS.

| | | | |
|---------------------------------------------------------------------------------------------------------------------------------|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|------|
| Aims of the Subsection of Plastic and Oral Surgery | 125 | Dental Anomaly: Report of Case of a Rudimentary Impacted Lower Third Molar | 51 |
| Anaphylaxis in Connection with Asthma, Hay Fever, and Various Skin Diseases | 1112 | Dental Bibliography: The Need of an Index of Periodical Literature | 128 |
| Asepsis vs. Antisepsis in Root-canal Procedure | 491 | Dental Clinic (The) in the National Army Cantonment | 704 |
| Apothesin, the New Local Anesthetic: Revised Technique of Pterygo-Mandibular Injection | 298 | Dental Clinics in Manila | 1115 |
| Band of a Gold Crown in the Bronchus: Report of a Case | 905 | Dental Engineering and the Normal Arch | 483 |
| Bearing of Physical Anthropology on the Problems of Orthodontia | 305 | Dentist or Stomatologist? | 980 |
| Brief Review of Current Dental Literature | 301 | Dentistry After the War: A Promising Professional Field for Young Men... .. | 806 |
| Cancer of the Oral Cavity | 774 | Diagnosis (The) of Malocclusion in Its Early Stages | 789 |
| Care of Children's Teeth | 911 | Effect (The) of Mouth Infection upon the General Health | 229 |
| Careful Technique the Greatest Factor in the Construction of Full Upper and Lower Dentures | 876 | Effects of Decayed Teeth upon a Child's Progress in School | 293 |
| Case (A) of Nasal and Palatal Restoration | 131 | Electrolytic Theory of Dental Caries: Observations on the Presence of Galvanic Phenomena in the Mouth; with an Annotated Commentary on Related Topics | 26 |
| Classification of Tissue Conditions in the Mouth as Related to Efficient Dentures | 996 | Evolution (The) of Orthodonty | 417 |
| Collapse under Anesthesia Due to an Enlarged Thymus Gland | 515 | Evolution of the Human Face: Chief Stages in Its Development from the Lowest Forms of Life to Man | 115 |
| Comparison of Office Policies (A) with Special Reference to Pulp Exposure or Death | 692 | Exercises for the Development of the Muscles of the Face, with a View to Increasing Their Functional Activity | 857 |
| Conduction Anesthesia | 1124 | "Exodontia" | 1006 |
| Conservation and Utilization of Cicatricial Bands in the Treatment of Jaw Fractures Involving Extensive Loss of Substance | 316 | Experimental and Clinical Study of the Isolated Thyroid Hormone | 133 |
| Conservation of Approximal Interspaces, Together with the Adjustment of Occlusal Relationships | 976 | First Line Trench (The) in Dentistry | 777 |
| Conservation of Time in Teaching Dental Students | 772 | Healthy and Diseased Conditions of the Alveolar Processes of the Jaws | 426 |
| Control (The) of Focal Infections | 963 | Hemorrhage and Its Treatment | 688 |
| Conversion of India Rubber into Vulcanite | 800 | Histological Pathology (The) of Alveolar Abscesses and Diseased Root-ends | 13 |
| Cysts of the Dental System | 555 | History of the Dental Society of the State of New York | 793 |
| | | Impacted Lower Third Molars | 101 |

| | | | |
|----------------------------------------------------------------------------------------------------------------------------------|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------|------|
| Importance of Dental Supervision During Pregnancy | 314 | Principles (The) of Black's Cavity Preparation | 1 |
| Importance of the Inter-articular Fibrocartilage of the Temporo-mandibular Articulation | 512 | Principles (The) Governing the Construction of Permanent Fixatures in the Treatment of Pyorrhea Alveolaris: With a New Method of Construction | 671 |
| Improved Method of Casting Splints, and Use of Headgear in Treating Fractured Jaws | 602 | Procaïn for Dental Operations | 966 |
| Indirect-Direct Gold Inlay Method | 328 | Radiolucency of Chloro-percha in the Radiograph | 433 |
| Influence (The) of General Health on Oral Tissue | 234 | Relation of Nasal and Oral Sepsis to Systemic Disease and Surgical Conditions Resulting from Focal Infections | 1003 |
| Influence of the War on Dentistry and Dental Colleges | 1001 | Relation of the Surgeon and the Dentist in Face and Jaw Injuries | 220 |
| Interpretation of Roentgenograms | 695 | Relationship of Oral Secretions to Dental Caries: | |
| Iodo-Glycerole | 50 | (I) Method of Determining the Amyolytic Index of Human Saliva | 140 |
| Logical Asepsis in Dental Practice | 31 | (II) Conditions Influencing the Quantity and Action of the Amylase Content of Human Saliva .. | 197 |
| Method of Taking Modeling Compound Impressions with the Mouth Closed and Under Normal Biting Strain | 225 | (III) Ferments of Human Saliva Other than Amylase | 287 |
| Minimum Requirements for Class "A" Dental Schools Adopted by the Dental Educational Council of America | 701 | Replanting <i>vs.</i> Apicoectomy | 473 |
| Movement of Teeth Predetermined by Engineering Instruments: Appliances Designed in Accordance with Analytical Mechanics | 39 | Report of a Case of Follicular Dental Cyst | 319 |
| Nature (The) of Pericemental Abscesses upon Vital Teeth | 570 | Report of the Committee on Practice (Dental Society of the State of New York) | 893 |
| Nature (The) of the Orthodontic Problem | 394 | Restoration of Abnormal Mouths by Surgical Treatment Before Inserting Plates | 414 |
| Nature's Tolerance and Compensating Adjustments as They Relate to Oral Restoration | 986 | Restorations with Jacket Crowns | 402 |
| Needs (The) of Prosthetic Dentistry .. | 1108 | Rôle (The) of Sepsis and Antisepsis in Medicine | 585 |
| Next Quarter Century (The) in Dentistry: A Prophecy Based on the Needs of the Profession and Our Hopes for Its Development | 1102 | Root Amputation (Correspondent's Report, Dental Society of the State of New York) | 914 |
| Non-cohesive Gold | 685 | Selection of Anesthesia for Oral Surgical Operations and the Roentgen Ray as an Aid in Diagnosis | 209 |
| Oral Anesthesia | 238 | Simple Form (A) of Removable Bridge Work with Cast Clasps | 204 |
| Orthodontic Treatment of Advanced Cases, and Patients Coming from a Distance | 45 | Some Experiences in the Camps and Fields of the Armies Overseas | 1119 |
| Past and Present of Operative Dentistry | 884 | Standardization of Root-canal Work .. | 498 |
| Pathogenesis and Prophylaxis of Pyorrhea Alveolaris | 659, 759 | Sterilization of Root-canals | 1071 |
| Pathology, Etiology, and Treatment of Pyorrhea | 574 | Success in Oral Restoration: What are the Fundamental Principles upon Which It Must be Based? | 785 |
| Pathogenesis and Treatment (The) of Pyorrhea Alveolaris | 781 | Suggestion (A) for Making Splints in Two Separate Parts and Their Union by Means of a Lock | 972 |
| Physiological Age: The Relation of Dentition to Body Growth | 899 | Surgical Correction of a Double Harelip, Alveolar Cleft, and Cleft of Hard and Soft Palate | 581 |
| Possible Relationship of Oral Focus to Chronic Osteomyelitis (a Case Report) | 147 | Technique (The) of Making Dental Radiographs | 232 |
| Practical Sterilization for the Dentist .. | 240 | Technique (The) of Root Amputation .. | 381 |
| Practice (The) of Dentistry in the Army and in Civil Life: A Comparison | 504 | Topics of the Day: Curretting, Ionization, Pulp Testing | 888 |
| Preliminary Report upon the Temporo-mandibular Articulation in the Human Type | 505 | Traumatism Due to Faulty Co-ordinating Bridge Work | 321 |
| Presence (The) of Taste Fibers in the Lingual Nerve | 217 | Treatment (The) of Pyorrhea Alveolaris | 992 |
| Primary Factors in the Etiology of Periodontoclasia | 1084 | Trichlorid of Iodin in Dentistry | 908 |

| | | | |
|-----------------------------------------------------------|-----|----------------------------------------------------------|------|
| Type of Denture (A) for Army Use .. | 516 | Vincent's Angina from the Oral Surgical Standpoint | 296 |
| Type vs. Temperament in the Selection of Teeth (IV) | 108 | When Shall Root-canals be Filled, and How? | 1093 |

Papers in Society Proceedings.

| | | | |
|---------------------------------------------------------------------|------|---------------------------------------------------------------|------|
| Engineering Principles Applied to Dentistry | 336 | President's Address (New Jersey State Dental Society) | 1019 |
| President's Address (Dental Society of the State of New York) | 809 | President's Address (Virginia State Dental Association) | 1033 |
| President's Address (Mississippi Dental Association) | 1041 | War Surgery | 1025 |

CORRESPONDENCE.

| | | | |
|------------------------------------------------------|-----------|-------------------------------------------------------------|-----------|
| Case (A) of Ptosis as the Result of Pulpitis | 709 | Radiolucency of Chloro-percha. 611. 708. | 808 |
| Case (A) of Tooth Gemination | 330. 807 | Replantation of Teeth | 613 |
| Dental Service in France | 148 | Scurvy-like Pyorrhea at "the Front" .. | 709 |
| Dentistry as a Career | 53 | "Self-limiting Action of Sulfuric Acid" | 1128 |
| "Iodo-Glycerole" | 612 | "Septic Teeth: Their Etiology and Surgical Treatment" | 241 |
| More Anent Standardization | 519 | Sterilization of Tooth Tissues with Silver Nitrate | 52 |
| Naval Dental Surgeon (The) at Work | 434 | Sulfuric Acid in Root-canals | 918. 1127 |
| Procain and Novocain Identical | 919 | "Technique of Root Amputation" .. | 520. 613 |
| Professional Capability and Dental Commissions | 918. 1129 | Unclean Yet Sound Dentures | 52 |

Dentistry in the War Zone.

(Illustrations.)

| | | | |
|-----------------------------------------------------------------|------|--------------------------------------------------|------|
| American Ambulance Hospital at Neuilly, dental department | 330 | Dental Clinic at St. Etienne | 1170 |
| Arrival (The) of the Dentist | 1009 | "Teaching Oral Hygiene to French Children" | 955 |

PROCEEDINGS OF SOCIETIES.

| | | | |
|-----------------------------------------------|--------------------|----------------------------------------|------------------------|
| Academy of Stomatology of Philadelphia | 250, 334, 614, 710 | Angle School of Orthodontia | 66, 159, 331, 435, 928 |
| Connecticut State Dental Association | 815, 1142 | Maryland State Dental Association | 1130 |
| Dental Society of the State of New York | 73, 809, 920, 1010 | Mississippi Dental Association | 1041 |
| Eastern Association of Graduates of the | | New Jersey State Dental Society .. | 54, 1019 |
| | | Northeastern Dental Association .. | 150, 242, 336 |
| | | Virginia State Dental Association | 1033 |

EDITORIAL.

| | | | |
|--------------------------------------------|----------|--------------------------------------------------------|-----------|
| Classification of Dental Schools | 937 | Oral Sepsis | 621 |
| Co-operation in Scientific Research | 821 | Pending Navy Dental Legislation | 344 |
| Dental Scientific Literature | 254 | Professional Appeal (A) | 81 |
| Dentistry in Relation to Reconstruction .. | 1149 | Proposed Legislation for Navy Dental Corps | 166 |
| Dentistry in the New Era | 441 | Rip Van Winkle, M.D. | 1049 |
| Expansion of the Army Dental Corps .. | 935 | <i>Status Præsens</i> (The) | 723 |
| Greene Vardiman Black Memorial | 824 | Transactions of the Inter-Allied Dental Congress | 826 |
| Industrial Dental Service | 521 | | |
| Jesse Cope Green | 163 | | |
| "L'Aide Confraternelle" Honor Roll | 348, 624 | <i>Corrections</i> | 524, 1052 |

BIBLIOGRAPHICAL.

| | | | |
|------------------------------------------------------------------------|-----|------------------------------------------------------------------------------------|--------------------------|
| American Illustrated Medical Dictionary .. | 349 | Manual (A) of Dental Prosthetics ... | 85 |
| Anatomy and Histology of the Mouth and Teeth | 625 | Oral Roentgenology | 84 |
| Army Dentistry (Forsyth Lectures for the Army Dental Reserve Corps) .. | 827 | Oral Sepsis in Its Relationship to Systemic Disease | 627 |
| Dental and Oral Radiography | 626 | Practitioner's (The) Medical Dictionary .. | 84 |
| Dental Electro-Therapeutics | 827 | Principles and Practice of Filling Teeth .. | 1152 |
| Essentials of Laboratory Diagnosis | 715 | Surgery and Diseases of the Mouth and Jaws | 257 |
| General Pathology and Bacteriology for Dental Students | 715 | Textbook on Dental Histology and Embryology, Including Laboratory Directions | 626 |
| Handbook (A) of Antiseptics | 524 | | |
| Inter-Allied Dental Congress | 525 | <i>Books Received</i> | 258, 526, 716, 828, 1153 |
| Lord Lister | 445 | | |

PRACTICAL HINTS, ETC.

| | | | |
|--------------------------------------------------------|------|-------------------------------------------------------------------------------|------|
| Amalgam Restorations for Gold Crowns .. | 95 | Dental Trocar (A) | 1154 |
| Application of Silver Nitrate in Root-canal Work | 1053 | Safe Way of Using a Separating Disk .. | 1158 |
| Casting Zinc Electrode Points for Ionization | 360 | Use of the Drill as an Aid to Tooth Extraction | 1157 |
| Dental Anomaly (A) | 539 | Vulcolox Anterioris in the Construction of Richmond Crowns and Bridge Work .. | 939 |

REVIEW OF CURRENT DENTAL LITERATURE.

| | | | |
|----------------------------------------------------------------------------|------|---------------------------------------------------------------------------------------------------------------------|-----|
| Aberrant Thyroid Tumor of the Tongue .. | 943 | Autogenous Oral Streptococcal Vaccines in the Treatment of Seventeen Cases of Sprue | 942 |
| Acute Suppurative Whartonitis | 832 | Bacterial Action of Arsenical Compounds on Experimentally Produced Streptococcic Septicemia | 830 |
| Alcohol Sterilization | 529 | Behavior of Hypochlorite and of Chloramin-T Solutions in Contact with Necrotic and Normal Tissues <i>in vivo</i> .. | 722 |
| Aleresta Ipecac | 87 | Bismuth Poisoning as Affecting the Oral Cavity | 451 |
| Alleged Dental Stigma (An) of Congenital Syphilis | 447 | Blepharospasm Secondary to Pyorrhea Alveolaris | 834 |
| Anesthesia and Antiseptics in Plastic Restoration of the Face and Mouth .. | 942 | | |
| Anesthesia and Respiration | 355 | | |
| Aneurysms of the Arteries of the Head and Neck | 88 | | |
| Asepsis and Antisepsis in Modern Dentistry | 1059 | | |

| | | | |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------|------|------------------------------------------------------------------------------------------------------------------------------------------|------|
| Bone-Grafting in Gunshot Wounds of the Mandible | 632 | Incidence of Chronic Focal Infection in Chronic Diseases | 354 |
| Cartilage Transplantation in Extensive Wounds of the Lower Jaw | 172 | Investigation of the Methods of Disinfection Carried Out in Dental Offices | 631 |
| Case of Chronic Nephritis: Uremia: Severe Hemorrhage from Gums | 530 | Infectious Ulcero-membranous Stomatitis and Gingivitis | 534 |
| Case of Congenital Angioma of the Tongue | 169 | Ionization Applied to the Treatment of Facial Cicatrices | 632 |
| Case of Meningitis Associated with the Presence of Bacillus Fnsiformis | 1160 | Kidney Infection as a Result of Pyorrhea | 449 |
| Case of Noma Following Paratyphoid B. | 1059 | Leucoplakia of the Tongue | 941 |
| Case of Pyorrhea Alveolaris Treated by Intramuscular Injections of Emetin Hydrochlorid | 259 | Lipoids (The) in Tumors of the Dental System | 831 |
| Case of Vincent's Infection, Involving Mouth, Eyes, and Penis | 87 | Localization of Streptococcus Viridans | 173 |
| Causes of Bad Breath | 532 | Loose Cartilage in the Temporo-maxillary Joint | 835 |
| Changes Produced in the Blood by Nitrous-Oxid-Oxygen Anesthesia | 633 | Macroglossia Lymphangioma, with Report of Case | 944 |
| Clasped Partial Dentures Versus Bridge Work | 629 | Mamillary Eminence (The) of Sabouraud: Its Clinical Significance | 447 |
| Clinical and Bacteriological Study of the Reinfection of Root-canals, especially After Treatment with Tricresol-formalin and Peruvian Balsam-iodoform | 720 | Maxillo-dental-facial Malformations ... | 1159 |
| Clinical Methods of Treating Hypersensitive Dentin | 88 | Measurement of the Force of the Jaws | 1058 |
| Comparative Efficiency of Local Anesthetics | 259 | Menace (The) of Mouth Infections .. | 167 |
| Dental Stigmata in Congenital Syphilis | 447 | Mercurial Stomatitis: Its Pathogenesis, Prophylaxis, and Treatment | 86 |
| Dentigerous Cysts, with Report of Case | 944 | Methods of General Anesthesia in Facial Surgery | 942 |
| Diseases of the Eye from Focal Infection | 834 | Microscopic Anatomy (The) of Chronic Periodontitis and the Pathogenesis of Dental Root-cysts | 174 |
| Disinfection of Pneumococcus-Carriers.. | 533 | Mixed Tumors of the Salivary Glands: A Study Based on the Experimental Production of Neoplasm in the Submaxillary Gland of the Dog | 837 |
| Endameba Buccalis: (II) Its Reactions and Food-taking | 262 | Mobile Bridges | 629 |
| Experimental Parotitis | 1160 | Modern English Skull (The) | 717 |
| Experimental Study of Root-filled Teeth: Preliminary Report | 450 | Multiple Primary Malignant Tumors .. | 1162 |
| Facial Paralysis in a Syphilitic | 1160 | New Case (A) of Heredo-syphilis Nerviosa | 447 |
| Facial Paralysis Following Pasteur Antirabic Treatment | 91 | New Continuous-Gum Set | 719 |
| Few Notes (A) on the Treatment of Gunshot Wounds of the Jaws | 172 | Non-union of War Fractures of the Mandible | 629 |
| Fibrin Paper as a Hemostatic Agent .. | 944 | Note upon Mottled Teeth | 631 |
| Fibroma of the Tongue, with Consideration of Other Tumors of the Tongue and Certain Technical Points in Tongue Resections | 837 | Oculo-cardiac Reflex in Cases of Contractures of the Jaws | 263 |
| Fifth Cusp (The) and Congenital Syphilis | 447 | Operative Treatment of Trigeminal Neuralgia | 940 |
| Focal Infection in the Etiology of Skin Disease | 836 | Oral Sepsis and the Anemias | 352 |
| Frequency of Vincent's Angina | 941 | Orokinase and Ptyalin in the Saliva of the Horse | 833 |
| Further Experiments with the Use of Bone-Grafts: Abstracts from Recent German Publications | 258 | Paget's Disease of the Bone | 451 |
| Giant-cell Epulis of the Upper Jaw .. | 528 | Paralysis of the Facialis Caused by Salvarsan | 170 |
| Gonococcus Infection of the Mucous Membrane of the Oral Cavity | 534 | Pathogenesis of Infantile Scurvy: An Hypothesis | 449 |
| Healing of Lower Jawbone Defects in War Cripples | 172 | Pathological Anatomy of Epulides | 528 |
| Herpes Zoster a Focal Infection | 86 | Perforating Ulcer of the Hard Palate Resembling Tertiary Syphilis, but Due to a Fusio-spirillary Invasion | 1160 |
| Impressions for Full Dentures, and a Technique | 168 | Persistent Chronic Apical Inflammation and Its Treatment | 169 |
| | | Porcelain Jacket Crown (The) | 260 |
| | | Present Status (The) of Dental Bacteriology | 171 |

ORIGINAL COMMUNICATIONS

The Principles of Black's Cavity Preparation.

By R. R. BYRNES, D.D.S., Richmond, Va.,

PROFESSOR OPERATIVE TECHNICS AND CLINICAL DENTISTRY, SCHOOL OF DENTISTRY,
MEDICAL COLLEGE OF VIRGINIA, RICHMOND.

(Read before the Virginia State Dental Association, Norfolk, Va., April 18, 1917.)

I HAVE been asked to talk on the principles of cavity preparation as set forth by Dr. G. V. Black. The subject is so extensive that in a talk of an hour you can readily understand I can simply touch it in its most essential features. In such a talk, therefore, it becomes a matter more or less of my personal viewpoint, founded on some years of teaching, as to what is most important. If I were asked to select the three most essential principles upon which this comprehensive system is built, I should probably answer: First, upon a thorough study and comprehension of the inclination of enamel rods in the different areas of the various teeth; second, upon the extension of cavity margins to areas of immunity, or, as it is usually termed, extension for prevention of the recurrence of decay; and third, the establishing of definite angles at the junction of the surrounding walls with the floors of cavities.

INCLINATION OF ENAMEL RODS.

No scientific cavity preparation can be attained without a thorough knowledge of the structure of enamel and dentin, which of course carries us into the realms of histology. May I, therefore, for a brief space recall to your minds what we learned in our college days, and with the aid of these charts refresh them in what must of course be a very superficial way, with the structure of enamel and dentin, but more especially the former?

Enamel is composed of rods or fibers held together by an intervening cement substance. The enamel rods in turn are made up of globules or little balls held together in rows or lines. These can best be likened, in a gross way, to the result one would obtain if he were to take small balls of putty or soft clay, and by stacking them one upon another apply just pressure enough to make them

flatten at their points of contact sufficiently to permit of their standing alone. If, now, several of these stacks or columns be placed in close contact, some idea may be obtained of the structure of enamel.

The enamel rods are stronger than the cement substance which binds them together, so that in breaking or cutting the enamel it is inclined to split along the length of the rods. This, then, is known as the line of cleavage, and is a most important feature in cavity preparation.

It is surprising to what extent the general rule applies that *The direction of the enamel rods is from the center of*

nature's effort to so present the ends of the rods as to best withstand the stress of mastication, or possibly more properly, incision or biting.

Our second diagram (Fig. 2) represents a central perpendicular section bucco-lingually through a bicuspid. In all of its parts the enamel rods are cut parallel with their length, but they do not all stand at right angles to the surface of the tooth. They do so most nearly in the central portion of the buccal and lingual surfaces, but as we near the region of the points of the cusps from both the occlusal and axial surfaces we find considerable inclination of the rods toward the points of the cusps, while

FIG. 1.

the crown of the tooth toward the surface, or, to modify this for practical purposes, that *The enamel rods are most commonly at right angles to the surfaces on which they are found.* In every tooth, however, there are certain portions in which the enamel rods approach the surface at more or less of an inclination from such a perpendicular.

With the aid of the charts I shall endeavor to set these before you.

In Fig. 1 we have represented a central perpendicular section through an incisor. You will note that the enamel rods are cut parallel with their length in all of its parts, but they are not all at right angles to the surface of the tooth. They are nearly so in the central portion of both the labial and lingual surfaces, but as we near the incisal there is sharp inclination in what would seem to be

FIG. 2.

in the region of the groove we find an opposite inclination. This, again, seems to be nature's effort to present as strong a "front" as possible toward the source of the stress of mastication.

The dotted lines extending from the horns of the pulp to the dento-enamel junction directly under the points of the cusps represent the recessional lines of the pulp, or the path along which the horns of the pulp receded as the tooth developed from its earliest to its present or adult stage. Time does not permit my going into this in proportion to its important bearing on cavity preparation. I can only say that their location in all teeth should be carefully studied.

It is here that unintentional exposure of the pulp very often occurs, for the reason that in the process of the development of the tooth and recession of the pulp this tract is not always completely

closed, and a slender thread of pulp tissue will often persist in the tract.

EXTENSION OF CAVITY MARGINS FOR THE PREVENTION OF RECURRENCE OF DECAY.

In taking up the second great principle mentioned in my opening statement, namely, extension of cavity margins for the prevention of the recurrence of decay, we must again lay a foundation by a short journey into other realms. This time it is pathology.

With reference to the manner in which teeth decay, there are two great groups, namely, pit and fissure cavities and smooth-surface cavities. The former are found wherever pits and fissures occur, *i.e.* upon the occlusal surfaces of bicuspid and molars, upon the occlusal third of the buccal surfaces of both upper and lower molars, upon the lingual surfaces of the upper anterior teeth—more often the laterals—and upon the occlusal third of the lingual surfaces of the upper molars where the disto-lingual groove extends over the marginal ridge on to the lingual surface and terminates in a pit. In a word, they are decays starting in structural defects.

Smooth-surface cavities, the other great group, and comprising by far the greater number of cavities, occur, as the name indicates, upon portions of the surfaces of teeth which do not present pits or fissures for the beginning of the process of decay. The process of decay, so far as the dentin is concerned, is identical in both of these groups, but the processes in the enamel are quite different and require different treatment in cavity preparation with reference to "extension for prevention."

Pit and fissure cavities occur in surfaces which are kept habitually clean by the excursions of food and saliva over their surfaces, but which, because of structural defects, permit lodgment of the micro-organisms in the recesses of the pits and grooves. Here they cover themselves with a gelatinoid substance which makes their hiding-place secure, so to speak. Their nest or nidus is thus

formed, and they grow and multiply. Their acid products dissolve out the lime salts which hold the enamel rods together, and thus form a channel for the progress of the micro-organisms toward the dentin and a general undermining of the enamel beneath the surface. This is termed backward decay. The only evidence upon the surface of such a process may be a darkened line in the groove or a spot in the pit, pressure upon which with a cutting instrument may cause the surface to cave in.

The process upon reaching the dento-enamel junction finds less resistance here than in the enamel, and the spread is more rapid. Because of the inclination of the enamel rods toward a groove or pit, we have the cone-shaped decay in

FIG. 3.

the enamel here, with its apex toward the surface and its base toward the pulp. The decay penetrates the dentin in the form of a cone with its apex toward the pulp, and its base toward the dento-enamel junction. Someone asks, Why cone-shaped in the dentin? Because the decay had its commencement in the center of the area involved at the dento-enamel junction. The dentinal tubules being entered there first, the micro-organisms penetrate farthest because of their early start. This whole process is shown diagrammatically in the occlusal portion of the tooth in Fig. 3, *a*. The cone is larger in the dentin than in the enamel because the dentin is preferable to the micro-organisms, is softer, etc.

In the preparation of cavities of the pit and fissure group, it is only necessary to remove the enamel covering the area undermined by caries, and form the cavity in the dentin. Further extension for

prevention of recurrence of decay is not necessary, except where it may be required to follow out deep grooves to places where a smooth margin may be given the filling or restoration.

Smooth-surface cavities have their beginnings on surfaces which are free from structural defects. Micro-organisms must therefore attach themselves to the surfaces in areas which are more or less hidden from the excursions of the food and saliva, as in the proximal surfaces, and in habitually unclean areas, left so by scant use of the toothbrush, as at the gingival of the buccal and labial surfaces. An example is shown on the diagram, Fig. 3, at *b*. Here again the micro-organisms collect and cover themselves with a gelatinoid substance, their acid products dissolving out the lime salts of the enamel, but because of the difference in the inclination of the enamel rods as compared with those at *a*, the decay spreads laterally on the surface, each part of the widened area of beginning decay penetrating in the line of the length of the enamel rods, which gives a conical area of decay with the base of the cone at the surface, the apex toward the pulp. This, you will note, is just the reverse of the process at *a*, while the decay in the dentin is identical. Or, to repeat, immediately the enamel is penetrated, decay spreads laterally along the dento-enamel junction in every direction. As each new dentinal tubule is reached, a spreading of the decay along it toward the pulp of the tooth occurs. In the first tubules entered it goes deepest because begun there first, this giving a conical area, as shown at *a*.

The extension of such a cavity as is shown at *b* from the center of the surface far toward the mesial and distal angles of the tooth is so necessary that the rule should be to cut close to the angles in every case, but never past the angles. Herein alone lies safety, for if this is not done, and susceptibility to caries continues, decay is almost sure to recur to the mesial or distal or both, and the filling will be lost. Why to the angles? Because this is an area of natural immunity. I might mention that in a record

of ten thousand cases examined in the dental clinic of the Northwestern University at Chicago but nine were found to have caries beginning at these angles of the teeth, and all of these had some natural or acquired fault of occlusion—teeth twisted, not occluding, or abscessed, thereby preventing normal use.

In laying the gingival wall of your cavity you should be guided by the age of the patient. If such cavities are filled in young persons without pushing the gingiva well back so that the margin of the cavity can be extended well under it, the natural shrinkage of the gingivæ as age advances will expose the enamel between the gingiva and the filling.

THE SEVEN STEPS IN CAVITY PREPARATION.

To some of you gentlemen, grown gray in the practice of your profession, it may sound cumbersome when I say that Black's system contemplates seven distinct steps in the preparation of cavities in the teeth. Both from my experience as an accountant and as a dental teacher, I am most willing to subscribe to the principle that "any system is better than none." This in no sense is an apology for the one I am expounding, for if I were not satisfied with its merits I should not teach it. I can go farther, and say, for the comfort of any who will adopt them, that with increased use these steps become almost second nature. We follow their sequence without realizing it, even as we drive our automobiles. I can at this time scarcely do more than recount, and give a brief explanation of each step.

(1) *Outline form*. This, in a word, is the mental picture we form of the area to be included in the finished filling or restoration. Yes, I grant you that we may have cause to change this as we open up the cavity, but is it not better to work with a definite end in view than to just cut and drill away until we conclude "That will do"? Conditions may not permit the preparation of an ideal cavity in many cases, but is it not better to have an ideal toward which to work,

even if we cannot attain it? Outline form, then, is the form of the area of the tooth surface to be included within the outline or enamel margins of the finished cavity. The laying out and cutting to these lines should be the first thing considered and accomplished. Here is where we first have use for our knowledge of the inclination of the enamel rods, as well as extension of cavity margins for prevention of the recurrence of decay. If the cavity be of the pit and fissure class it means, in addition to breaking down all undermined enamel, the following out of grooves to a point where a smooth finish may be given the margin of the filling. If of the smooth-surface group, it means the laying of cavity margins in areas of immunity or those areas kept clean by the excursions of food and saliva over their surfaces.

(2) *Resistance form*. This is the form given a cavity to best enable the restoration or filling to withstand the stress of mastication, and is accomplished in its highest form by combining a flat seat or floor for the filling, cut at right angles to the direction of the stress of mastication—which is usually at right angles to the long axis of the tooth—together with definite angles at the floor junction with the surrounding walls. *A round bur has no place here*. This, then, is our first encounter with the third important principle mentioned in my opening remarks, namely, the establishment of definite angles at the junction of the surrounding walls with the floors of cavities.

(3) *Retention form* is the form given a cavity to prevent the filling from being displaced by such lateral or tipping force as may be brought against it. In simple cavities the retention form is obtained by so placing the opposing walls as to make them strictly parallel, or *slightly*—and I want to accent that word “slightly”—undercut in order that the filling material may be firmly held in place. Retention form is required in its most perfect aspect in proximal cavities on bicusps and molars, and is made in the form of a step cut over on the occlusal surface in more or less the shape of a dovetail. Let me impress upon you that in

the use of this step you do away with unnecessarily deep cavities on the proximal surfaces, and it should always be used, unless, perchance, the tooth which would ordinarily approximate the filling is to be permanently absent. Formerly, pits and grooves were depended upon for retention form, but they have proved “a delusion and a snare.” The pot-leg, made usually with a round bur, has no place in modern dentistry.

(4) *Convenience form*, though not of such prime importance as other steps, should not be neglected. It represents certain modifications in a cavity which will render the form more convenient for placing the filling material; often, by cutting a wall to a certain inclination the plugger point will reach some portion, or at a more available angle, enabling the operator to pack gold more accurately and securely in certain otherwise inaccessible parts of the cavity. This is exemplified in the proximal cavity on a cuspid by cutting past the mesiolabial angle somewhat on to the labial surface.

A second order of convenience form consists of slight undercuts (not pot-legs) placed usually in point angles to serve as starting-points for packing gold. A point angle in dentistry is where three walls meet. In proximal cavities they are placed in the axio-linguo-gingival and axio-bucco-gingival angles, and should rarely be placed below the level of the gingival wall. They should be cut at the expense of the buccal and axial, or lingual and axial walls. They should be in the shape of a wedge or cone with its base at, not in, the gingival wall, and tapering off to nothing half-way up the axial wall, so to speak.

(5) *Removal of remaining carious dentin*. Before proceeding to this step the rubber dam should be applied, for should the pulp be exposed in the accomplishment of this operation we find ourselves in better position to master the situation, and proceed in more nearly aseptic surroundings.

Generally, when the cavity has been given the treatment thus far mentioned, there will be no carious dentin remain-

ing, but in the larger cavities it will often be a question whether or not the pulp will be exposed in removing the carious dentin overlying it. Do not, therefore, cut toward the pulp until the cavity is otherwise prepared, as it will then be easier to give an exposed pulp the treatment which may be indicated. When this stage in cavity preparation is reached, any remaining softened dentin may be removed with large spoon excavators. Very often, by working around the edges, a large cake of leathery decay may be lifted off a pathological pulp almost painlessly, whereas the patient would not allow you to "get near it" by going in at the center.

(6) *Finishing the enamel walls and beveling the cavo-surface angles.* If your treatment of the enamel walls thus far has been done with a proper observance of the inclination of the enamel rods, there will remain little to be done now so far as smoothing is concerned, other than running over them with a planing motion with a sharp chisel. When the walls have been satisfactorily smoothed the cavo-surface angle of the enamel should be cut to a distinct bevel outward, also by a planing motion with a chisel, enamel hatchet, or gingival margin trimmer, used lightly. This bevel should include about one-fourth the thickness of the enamel wall, and should be at an angle of from six to ten centigrades from the plane of the enamel wall. The object is to cut away any loose ends of or any unsupported enamel rods which might afterward fall away and render the margin imperfect. We have all seen the dark outline surrounding the *other fellow's* fillings. A second object is to safeguard the cavo-surface angle against possible checking in packing filling material. I am asked so often if this may not be done with small stones and even fissure burs in the engine, that I am going to answer right here, No, not in my hands, for with such an agent I lose that tactile feature which is so valuable in this delicate work. If I were to use a stone at all, it would be an Arkansas stone, and that only succeeding my cutting instruments, for I would value only

its polishing characteristics. Sometimes, when the walls are just right, a very fine polishing strip may be used on cavities in the anterior teeth, but this merely supplements, not supplants, the sharp cutting instruments.

(7) *Cavity toilet* consists in freeing the cavity from chips and dust then remaining. This should be done by wiping the cavity in all its parts very thoroughly with dry cotton or spunk held in the pliers. Do not use alcohol, for after drying with the air-syringe something will be left coating the walls.

Let me give you this final rule with all the force at my command: *If, after all the cutting is done, moisture of any kind should enter the cavity, that portion of the cavity should be thoroughly dried and freshened with the cutting instruments.*

PREPARATION OF CAVITIES BY CLASSES.

You will remember I said that with reference to the manner in which they decay, cavities are divided into two groups, pit and fissure cavities and smooth-surface cavities. Now, with reference to the similarity of treatment and instrumentation, they are divided into five classes, as follows:

Class I—Pit and fissure cavities, found wherever structural defects occur.

Class II—Proximal cavities on bicuspid and molars.

Class III—Proximal cavities on incisors and cuspids which do *not* require the removal and restoration of the incisal angle.

Class IV—Proximal cavities on incisors and cuspids which *do* require the removal and restoration of the incisal angle.

Class V—Gingival third cavities—not pit cavities—occurring on the labial, buccal, or lingual surfaces of the teeth.

An analysis of this classification will reveal the fact that class I and group 1 are identical, *i.e.* pit and fissure cavities, while classes II, III, IV, and V, comprise group 2, or smooth-surface cavities.

Class I cavities. To take up the preparation of a simple cavity of class I (see Fig. 4) in the central fossa of

the occlusal surface of an upper first molar: Such a cavity would come to us with a dark spot as its only outward evidence, while examination with the aid of an exploring tine would reveal the fact that it was more or less undermined—"backward decay" in other words.

To obtain outline form (our first step) a round bur 8/10 mm. in diameter is placed in the pit while in rapid rotation, and the handpiece swayed to and fro to more readily engage the minute blades. A fair amount of pressure is used until the bur enters the dentin. If, however, it does not do so readily, it should be removed and allowed to cool. After entering the dentin it should be

tained together. An inverted-cone bur 1 mm. in diameter, held with its square end against the pulpal wall or floor, is carried entirely around the floor, making a sharp angle at its junction with the surrounding walls. The pulpal wall is at the same time made flat, thereby obtaining the resistance form. Do not make the cavity deeper, merely broader. The cavity should be made as shallow as the removal of all decay and proper seating in the dentin will permit.

No convenience form (step 4) is necessary in so far as access is concerned, though, for a gold filling, one or more convenience points sunk in the surrounding walls only—not in the floor—may be necessary.

It is well to apply the rubber dam here.

In a cavity of this size there is not likely to be necessity for our fifth step, the removal of remaining carious dentin, as it will more than likely have already been freed of caries by our previous instrumentation. If, however, there is carious dentin remaining, it should be removed with spoon excavators 10-6-12.

The next is the sixth step, or smoothing of cavity walls and beveling of cavo-surface angles. This is done by careful paring or planing with a sharp chisel of suitable size, in the direction of the margin of the cavity or around the cavity. In such a cavity as this the inclination of the enamel rods will be toward the cavity, and so the enamel walls may be left parallel with each other without fear that any will be left unsupported, but the cavo-surface angle of the entire margin should be slightly beveled to diminish danger of fracturing the otherwise sharp margin in placing the filling material.

There now remains but one step, the cavity toilet, which, as mentioned before, consists of wiping or sweeping the cavity clear of all dust and débris.

Class II cavities. In our bicuspid model (Fig. 5) we have an example of class II, or a cavity on the mesial surface of a bicuspid. Remember that the occlusal surface was intact when such a case presented. Remember also that this occlusal portion or "step" represents re-

FIG. 4.

removed from the handpiece and followed with a similar bur 1 mm. in diameter, the orifice being enlarged therewith. This completes the use of the round bur, and is its *only use* in the excavation of cavities. Any further opening of the cavity found necessary is obtained with inverted cone burs and hand instruments. The cavity should now be extended to include the sharp slopes toward the pit, without making its floor deeper. This broadening is done by undermining the enamel with an inverted cone bur 8/10 or 1 mm. in diameter. The undermined enamel is then chipped away with straight and binangle chisels and enamel hatchets until the margins are laid in smooth areas, which is all the extension for prevention necessary on this surface, kept habitually clean by the food and saliva.

In this cavity, resistance form and retention form (steps 2 and 3) are ob-

tention form, and should not be confounded with extension for prevention, which latter is exemplified in the proximal portion of the cavity by laying the buccal and lingual margins in the immune areas near the axial angles of the tooth.

Outline form. There are three methods of opening into such a cavity. The first plan is to enter the distal terminus of the groove on the occlusal with a bibeveled drill 8/10 or 1 mm. in width, cutting until the dentin is reached. Enlarge with a larger drill or inverted-cone bur. Follow out the groove toward the mesial, sinking it each time to the dentin and drawing to the surface until the mesial marginal ridge is cut through.

FIG. 5.

Enlarge this slot till the dovetail is formed and has been widened and deepened sufficiently at the mesial to partially uncover the decay in the mesial surface.

The second plan is to place a sharp chisel in the center of the mesial marginal ridge, inclining it first toward the buccal and then toward the lingual, repeatedly tapping it with a mallet until a V-shape is cut in the ridge. Enlarge this by the same procedure until the cavity of decay is reached and uncovered. A bibeveled drill may then be placed therein and made to penetrate the dentin. The cut into the cavity may then be made with the inverted-cone bur. After sufficiently enlarging this the bur should be engaged in the dentin close to the dento-enamel junction, pressing it distally along the line of the occlusal

groove, the slot, and then the dovetail may be cut in the occlusal surface.

The third plan is to place a separator in position, lift the teeth apart sufficiently to admit chisel No. 10, or the smaller width hoe (6 angle), approaching the cavity from the buccal direction. Its position may be gradually shifted to the occlusal as the enamel is chipped away closer to the marginal ridge, until finally the enamel of the ridge itself may be chipped away by holding the instrument in the occlusal direction. An inverted-cone bur may then be used for opening up the occlusal surface, as in the second method. Do not make the mistake of making the occlusal step too narrow. It should occupy about one-third of the occlusal width of the tooth bucco-lingually. This may be done with repeated underminings with the burs and chipping with sharp chisels.

Because of the inclination of the enamel rods toward a groove, the walls in the occlusal step may be made to parallel each other in the enamel as well as the dentin. In this position the outer extremities of the enamel rods will be at the enamel wall of the cavity, while the other extremities will be resting in the dentin.

In cutting the proximal portion to outline form, enamel hatchets 15-8-12 should be used to trim the overhanging enamel from the buccal and lingual walls. Often the straight and binangle chisels may be used for this. Then the gingival wall is cut with a scraping motion until sound dentin is reached. The buccal and lingual walls should be cut well toward the axial angles of the tooth, the extent being determined by the width of the embrasures, and should be sloped outward, in line with the inclination of the enamel rods in this locality. If much cutting is necessary, it may be accomplished with the aid of a small inverted-cone bur introduced close to the dento-enamel junction about the center of the gingival wall, and cuts made buccally and lingually, squaring the bucco-gingival and the linguo-gingival angles. The bur should then be drawn toward the occlusal in the dentin of both the

buccal and lingual walls, thereby undermining the enamel, which is easily chipped away by introducing the chisels in the buccal and lingual embrasures. The lingual wall should be cut so that its margin may be seen past the approximating tooth when looking across the central incisors at the median line. The buccal wall should be cut to correspond. A very good test is to cut into the embrasures far enough to just permit of the insertion of a chisel, past the approximating tooth, from the buccal and lingual, so that its flat side will be in a plane parallel with the enamel wall. It will be readily seen that this gives a flare to the buccal and lingual enamel walls, made necessary by the enamel cleavage. The strongest seating is given your restoration or filling, however, if the corresponding dentin walls can be made parallel. Do not, nevertheless, cut your cavities too deep in an effort to accentuate this. If your cutting has been correct, the gingival wall in both the enamel and dentin will be on the same horizontal plane. This wall should be laid well past the original contact point, and as near the gingiva as practicable, the best results being obtained if it can be laid beneath it. Beware of leaving any chalky or etched enamel here. The junction of the gingival with the buccal and lingual walls should be sharp and definite in the dentin, but very slightly curved in the enamel.

Resistance and retention form in this cavity require that in the step portion the floor or pulpal wall shall be flat and the surrounding wall parallel, with a slight dovetail effect in outline; in the proximal portion the gingival wall will be horizontally flat, and meet the three upright walls, *i.e.* axial, buccal, and lingual, practically at right angles. The axial wall should meet the buccal and lingual walls at right angles in the dentin, the buccal and lingual walls being as nearly parallel as possible. Of course these latter in the enamel will necessarily flare, as stated before. The squaring of all line angles (wherever two walls meet) is done with chisels and enamel hatchets.

Convenience form in this cavity is ac-

complished with the cutting of wedge-shaped convenience points at the gingivo-axio-buccal and gingivo-axio-lingual point angles, as described before. Let me impress again that these are in no sense "pot-legs," and are accomplished with the smallest inverted-cone bur, No. 33½, together with chisels or enamel hatchets. These are needed only for starting gold fillings, though they may not be objectionable for plastic restorations.

Any remaining decay should be removed with the spoon excavators after first applying the rubber dam.

FIG. 6.

The walls should now be smoothed and the cavo-surface angles beveled in all parts. The latter is accomplished in the proximal portions with gingival margin trimmers having 80 in the formulæ for mesial cavities, and with those having 95 in the formulæ for the distal cavities. A careful examination of these instruments will disclose the logic of this and show how admirably they are designed for this work.

The cavity toilet is performed as before.

Class III (see Fig. 6), you will remember, is proximal cavities on the incisors and cuspids which do not involve the re-

removal and restoration of the incisal angle. With men of your intelligence and experience it is not necessary to go into their preparation step by step. A careful examination of the illustration herewith will show that, so far as the dentin is concerned, the cavity is given a triangular or wedge shape, with the gingival wall forming the base, while the apex is formed by the juncture, in a sharp acute angle, of the labial and lingual walls at the incisal portion. The axial wall or floor meets these three surrounding walls at right angles, and convenience points are made in the surrounding walls, not in the floor, at the three corners, so to speak. The outline of the cavity in the enamel is more or less oval, not elliptical. This form in the enamel combines a knowledge of the direction of the enamel rods with an observance of the esthetic, which you know teaches that curves are more beautiful than straight lines.

One particular feature to which I would call your attention is the laying of the labial margin well on the labial surface. Here we have a combination of convenience form or access with the esthetic, for it is better to expose to view the unmistakable evidence of a good gold filling than the hidden gold filling which gives to the enamel that discolored appearance so easily mistaken for decay and an ill-kept mouth.

It can readily be seen that the sharp angles and convenience points in the dentin establish undercuts sufficient to make it impossible to dislodge a filling.

Class IV (see Fig. 7) is in principle a class III cavity in which the decay has progressed so far as to necessitate the removal and restoration of the incisal angle. I have set forth the treatment of such a cavity in the model of a central incisor.

Here you will note we have a rather complicated form, and I have chosen it purposely. So far as the proximal portion is concerned, it is prepared, as far as it goes, after the same principle as the previous cavity—the two gingival convenience points included—with the exception that here you will note a slight

convexity of the floor or axial wall, in an effort to avoid exposure of the pulp. This makes its junction with the labial and lingual walls a little less than a right angle or more acute. However, the labial and lingual walls are erected in planes which are parallel in the perpendicular, but slightly converging as they extend toward the incisal. This gives the secure wedge form which prevents dislodgment toward the incisal, while the trench, so to speak, which is cut in the incisal edge of the tooth, between the labial and lingual enamel plates, together with the convenience point placed at the distal termination and in the floor of this slot or trench, makes it additionally secure

FIG. 7.

against tipping to the mesial. You will also note that in the incisal step portion more of the lingual plate of enamel is removed than the labial. This is because the stress of mastication is normally from the lingual in the upper anterior teeth. Were this a lower incisor the labial plate would be sacrificed more than the lingual, for the reason that the stress is just the reverse. You will note the "rounded corner" in the enamel at the junction of the proximal with the incisal portions of the cavity. This is to add strength and to prevent fracture with plugger points. Also please note that the incisal step is cut to about the junction of the middle with the distal third of the tooth, which is the point where these respective lobes of the tooth coalesce. This is a weak line, hence we should cut to or past it and not just *nearly* to it. This incisal step or slot

is cut with the smallest sizes of inverted-cone burs which give at once our outline, resistance, and retention forms.

Class v (see Fig. 8) is cavities in the gingival third, not pit cavities, of all the teeth. I am in the habit of referring to these in lecturing to my classes as "filth cavities"—a little strong, perhaps, but it drives home the point that most of these could be prevented by the use of a toothbrush and water four times a day.

I have elected to prepare one of these in my models on the buccal surface of an upper first molar. So far as the principles involved in the preparation of this class of cavities are concerned, they are

FIG. 8.

simple. So far as the practical preparation of this class in the mouth is concerned, these cavities are sometimes most difficult, first because of lack of access, and second because of extreme sensitiveness. The hand instruments will be found less painful than the burs. The first strokes are usually the most painful, but if well and vigorously made, most of the decayed material in the central portion can be removed. This should be followed with a sharp inverted-cone bur about 1 mm. in diameter, passed quickly around the periphery, with its square end resting upon the floor or axial wall of the cavity. Cut these cavities to but not over the angles of the teeth, which you will remember are the immune areas. Remember again that the age of the patient must guide you in laying the gingival margin of these cavities. You may find it necessary to use the square-end fissure bur in squaring up the mesial

and distal walls, which are liable to be too much undercut or marred by the inverted-cone bur. These cavities need almost no resistance form, except as it is included in the retention form, for the reason that they are not subjected to any stress. Convenience points for starting gold may be used as required, the maximum number being four, one being placed at each theoretical point angle, but scarcely more than two will ever be found necessary, and often none at all, depending upon the skill of the operator.

I have said so much about extending to immune areas that I want to relate what happens when this practice is ignored. Take, for example, this last cavity (Fig. 8). If the central part is cut out and filled without extension, the growth of micro-organisms will recur on the filling, and being unable to make any impression thereon, the nidus or nest will spread over it mesially or distally, or both, and decay of the contiguous enamel quickly ensues.

CUTTING INSTRUMENTS USED.

I do not feel that my talk would be even nearly complete without some mention of the system of cutting instruments devised by Dr. Black, and the scientific principles on which they are constructed. Time will not permit me to go into the detail of their logical and systematic arrangement, their different uses, etc., but I want to say that, besides having them make a certain number of these instruments, my classes are required to learn, among other things, their arrangement. This is done by class drills wherein some become so proficient as to be able, from the time of a complete disarrangement, to replace each instrument in its proper position in as short a time as four minutes. A complete set consists of 102 instruments; a long set, 51 instruments, and a short set, 25 instruments. The University set consists of 48 instruments, arranged after a definite, logical plan. They are made upon scientific principles, and a descriptive formula is stamped upon each handle. For the straight instruments, as, for example,

straight chisels, this formula consists of but one number, and represents the width of the blade in tenths of millimeters. Thus we have the three straight chisels, 20, 15, and 10, the first being 20 tenths or 2 mm. wide, the second being $1\frac{1}{2}$ mm., and the third 1 mm. in width.

All binangle (two-angle) and triple-angle instruments, with one exception, have three numbers in their formulæ—as, for example, chisel 20-9-6. The first represents the width of the blade in tenths of millimeters, the second the length of the blade in millimeters, and the last is the angle of the blade in centigrades. This last, in a word, represents how much the blade deviates from the straight line of the handle or shaft.

In gingival margin trimmers, the exception referred to, we have four numbers in the formula. The additional one, which comes second in the formula, rep-

resents the angle of the cutting edge, which you will note is not at right angles to the long axis of the blade as in all others. Those with 80 in their formulæ are used for beveling the cavo-surface angle of the gingival wall of a mesial cavity, while those with 95 in their formulæ are used similarly in distal cavities.

In addition to these figures, where instruments are made in pairs the additional R or L for right and left is added to the formula.

To paraphrase an old aphorism, it can readily be seen what an immense advantage it is to have “A place for every instrument and every instrument in its place.” It can also be seen of what value it is to us in our infirmity work to be able to call for an instrument by name and formula, and have the student hand it to us without a moment’s hesitation.

219 N. BOULEVARD.

The Histological Pathology of Alveolar Abscesses and Diseased Root-ends.

By KURT H. THOMA, D.M.D., Boston, Mass.,

LECTURER ON ORAL HISTOLOGY AND PATHOLOGY, HARVARD UNIVERSITY DENTAL SCHOOL;
INSTRUCTOR IN DENTAL ANATOMY, HARVARD MEDICAL SCHOOL.

(Read before the New Jersey State Dental Society, Atlantic City, July 12, 1917.)

THE microscopic study of diseases or lesions is not only of great interest to the pathologist, but of far-reaching practical importance in laying the best foundation upon which to base intelligent and successful treatment.

Alveolar abscesses, caused by diseases of the dental pulp, involve two distinct chains of pathological processes. The first is spoken of as the acute alveolar abscess, and represents a process of destruction in which the tissue is dissolved into pus, while the second is rather of a constructive nature, producing inflammatory new growth in the cancellous part of the bone.

THE ACUTE ALVEOLAR ABSCESS.

The acute alveolar abscess is caused by a large invasion of pyogenic bacteria, and is accompanied by a violent reaction in the tissue. The bloodvessels, after an initial constriction, become dilated to almost twice their size, and leucocytes accumulate along their walls. A serous infiltration with emigration of polymorphonuclear leucocytes occurs in spaces formed between the fibers of the peridental membrane. This causes a rapid increase in size of the membrane, tending to push the tooth from its socket, and gives the impression of an elongated tooth. This phenomenon represents what clinically we call acute periodontitis. If the condition continues, tissue destruction sets in, and we find small necrotic areas. In a comparatively short time the pus col-

lects in larger quantity, and the bone of the alveolar socket becomes involved. The fibers of the peridental membrane swell, but still persist, and not unless suppuration is very active and prolonged

FIG. 1.

Photograph of a skull showing bone destruction due to a granuloma on an upper bicuspid.

do they become destroyed. After the destruction of the stratum durum of the alveolar socket, the surrounding cancellous part of the bone is freely infiltrated with pus, and we have the picture of the acute alveolar abscess. The Haversian canals are next involved, by means of

which the pus finds its way through the outer cortical layer of the bone. The periosteal tissue reacts at once, causing a local infiltration of polymorphonuclear leucocytes and a widespread serous infiltration, which causes large edematous swellings in the cheek or neck. The pus forms first under the periosteum—subperiosteal parulis—which has a remarkable resistance. After the periosteum has finally been penetrated, necrosis continues in the submucosa of the gum, ex-

FIG. 2.

Photomicrograph of a root-apex showing the beginning of a granuloma. The inner part shows darker, due to infiltration of inflammatory cells.

tending to its surface until it forms a fistula, which gives exit to the accumulated pus.

After the process of destruction has reached its climax, nature makes an attempt at healing by the formation of granulation tissue. The necrosed cells are dissolved by the leucocytes and either absorbed or expelled through the sinus. Fibroblasts and vascular endothelium are formed to replace the necrosed tissue. Unless the cause is removed, however, destroyed cells and serous or purulent exudation continue to pass through the newly formed tissue to the surface, while endothelial leucocytes and lymphocytes collect in large numbers in the deeper

layers of the granulation tissue to counteract the irritating agents absorbed from the exudates. This condition, clinically called chronic abscess, may last for an unlimited period, the discharge from the fistula increasing at times if the process of destruction becomes more marked; or it may become less, or even stop entirely at times, so that the mouth of the fistula becomes closed.

FIG. 3.

Photomicrograph of a tooth-root with dental granuloma. Note the infiltration of inflammatory cells between the fibrous tissue.

Nevertheless, it will reopen with more or less marked subacute symptoms when the suppurating process has overcome the defensive processes of the body.

DENTAL GRANULOMATA.

In contrast to this process of acute inflammation stands the dental granuloma, an infectious granuloma, which is placed pathologically between pure inflammation and neoplasm. It is, however, not a tumor, as the microscopic picture is distinctly that of chronic inflammation.

FIG. 4.

FIG. 7.

Photomicrograph of a granuloma with an acute process of suppuration which has penetrated the capsule and formed a sinus into the mouth.

Neither is it a process of pure inflammation, as the injurious agent does not produce actual destruction of the tissue, such as occurs in acute or suppurative inflammation. The lesion represents a reaction to a mildly injurious agent, such as bacteria in small numbers and of low virulence, or chemical irritants, such as formaldehyd, as well as toxins produced by bacterial action. The reaction pro-

FIG. 8.

duced is of a purely infectious nature, causing proliferation of the fixed tissue elements with round-celled infiltration. The granuloma is formed where the injury occurs, and this is usually at the apex of the tooth. However, if the tooth is perforated at the side of the root or at the bifurcation of a multi-rooted tooth, it results in a lateral or inter-radicular granuloma.

The granuloma increases at the ex-

pense of the surrounding bone. After part of the stratum durum of the alveolar socket has disappeared, it grows into

FIG. 9.

the medullary spaces, and the lamellæ and trabeculae of the cancellous part of the bone become resorbed, although oc-

casional parts are encapsulated in the granuloma. This process may not be restricted to the inner part of the bone, as the outer cortical layer quite frequently becomes involved, especially if the apex of the tooth is situated near the surface of the bone. This is shown in one of the illustrations.

increase in the number of cells in the focus, we have the formation of plasma cells as an important feature. These become very abundant, and are seen as cells with irregular cytoplasm, and from one to four nuclei in excentric arrangement. While all this is taking place the lesion gains in circumference, and while it may

FIG. 11.

Simple dental granulomata. The reaction which is caused by the injurious agent consists of a proliferation of the fibroblasts and vascular endothelium of the periodontal membrane. The part nearest the source of the injury becomes infiltrated with lymphocytes and a small number of leucocytes, and this focus of inflammation becomes surrounded by a fibrous layer which is continuous with the periodontal membrane. Besides the

occasionally attain very large proportions, it is usually about the size of a pea.

At this stage the simple granuloma is surrounded by the fibrous capsule, which extends into the medullary spaces between the trabeculae of the bone. This is the reason why, in most cases, the granuloma is held back in the jaw when the tooth is extracted. It is, however, occasionally connected so firmly with the periodontal membrane that it is attached

to the extracted tooth. The thickness of the capsule varies greatly. The fibers are arranged in bundles and grow in various directions, as can be well demonstrated with special stains, viz, such

greatly increased, and contain red corpuscles, a granular substance, and occasionally polymorphonuclear leucocytes. The endothelium often shows a proliferating appearance. Besides fibro-

lation. Bacteria and toxins may therefore be carried away by the blood stream.

The inside of the granuloma appears at first to be one great mass of plasma

laries. Polymorphonuclear and endothelial leucocytes and eosinophils may be found in large or small numbers, according to the special condition which pro-

cells, but careful examination reveals capillaries, often lined by only a single layer of endothelium. These are especially abundant in young specimens.

duced the tissue reaction. Erythrocytes are sometimes seen in various parts of the granuloma, and are usually due to the extraction of the tooth, which causes

a rupture of the extended vessels. The infiltration is generally centered around the apex of the tooth, and the inflammatory granulation tissue quite frequently extends part way into the root-canal, which may explain some clinical observations which interfere with successful root-canal treatment.

matory condition causes a proliferation, and we find dividing and branching chains of epithelial cells which grow like a network through the lesion. In a section they show as bands of uneven thickness radiating in various directions. The cells of the proliferating epithelium differ in appearance from the cells of the

FIG. 19.

Roentgenogram of a periodontal cyst which apparently was formed from an epitheliated granuloma at the apex of the devitalized lower first bicuspid.

Epitheliated dental granulomata. Remains of the embryonic enamel organ are often found in the normal periodontal membrane of animals as well as man. They can easily be seen under the microscope, occurring in small groups, islands, or chains. The presence of epithelium is not constant in the periodontal membrane, and therefore is not regularly found in the dental granuloma. However, if epithelial cells enter into its formation, the irritating influence of the chronic inflam-

epithelial islands; they become large, and the cytoplasm and nucleus grow more distinct. Leucocytes and plasma cells often invade the intercellular substance which loosely connects the various cells.

Dental granulomata showing necrosis and suppuration. Quite frequently we find one or two places in the granuloma where necrosis has taken place. A certain number of cells are seen detached from the rest, and are more or less broken down. Polymorphonuclear leucocytes are

then found in large numbers in the capillaries and the tissue where the process of destruction is going on. The pus which

is formed is absorbed, and this halts the infiltration of leucocytes, and leaves a space or spaces in the central part of the granuloma. Such a space is called a

lumen, and may contain remnants of the decomposed tissue and inflammatory excretions from the root-canal or remaining part of the lesion. The process of suppuration is usually caused by bacteria which emigrate from the root-canal or are forced into the granuloma through instrumentation. It is seldom very severe, and is usually taken care of by the defensive forces of the body, which cause absorption of the pus. Occasionally,

FIG. 22.

that they are of infectious nature. Roentgenographic examinations give further evidence of this by demonstrating that

such cysts are almost always connected with a devitalized tooth, except in cases where the tooth has been extracted without removing the epithelial granuloma or the partly formed cyst.

Dental granulomata showing various retrograde processes. Besides necrosis and suppuration we find most frequent evidence of cholesterol formation, especially in old specimens and periodontal

FIG. 27.

Photomicrograph of apex of a tooth with granuloma. Note that the granulation tissue extends into the root-canal, and that the apical part of the root-canal has been covered by layers of new cement.

cysts. Cholesterol crystals can be recognized by the rhomboid spaces left by the crystals which dissolve during dehydration in alcohol. They can be demonstrated, however, in frozen sections, in which they appear as brownish crystals. Foreign body giant cells frequently surround one or more of these crystals, as seen in one of the illustrations.

Occasionally fatty degeneration occurs, usually at the periphery just inside the

fibrous capsule, and collagen is often formed by the fibroblasts in large quantities from the fibrin of the inner part of the granuloma. This can be well demonstrated by Mallory's anilin-blue stain, which stains the fibrin and fibrogia fibers red and the collagen blue. Hyalin is found quite frequently. It accumulates in drops of various sizes in the cytoplasm of the plasma cells—Russell's fuchsin bodies. Often the entire cell is so filled with hyalin that the nucleus is pressed to one side, and nothing remains of the cell but the acidophilic hyalin bodies and a crescent-shaped nucleus.

All of these retrograde processes are shown in one or the other of the dental granulomata studied.

THE EFFECT OF ALVEOLAR ABSCESS ON THE ROOT-ENDS.

Acute or chronic inflammation of the peridental membrane, when of long standing, leaves its mark on the apex of the root.

Necrosis of the root-end. If the apical part of the peridental membrane has become destroyed, or if its blood supply has been disturbed, we have a condition which entirely inhibits the metabolism of the tooth. The cementum, which is porous, then easily absorbs the products of inflammation, and becoming infected, forms an obnoxious foreign body, which nature tries to eliminate. Absorption starts at the surface, and soon the cementum presents a roughened appearance, but this is too minute to show in a roentgenogram. It is, however, easily recognizable under the microscope. Occasionally the infection penetrates the cementum at some point, and spreads rapidly between the dentin and ce-

mentum in a peripheral direction. More frequently, though, we find that osteoclasts form in large numbers along the surface of the tooth, producing well-marked indentations. The osteoclasts are of irregular and varying shapes, with one, two, or more nuclei. They are often connected with the tooth surface by fine processes. The absorption of the tooth root is very slow, and differs somewhat from the same condition occurring in bone. There the necrosed portion may finally separate and be expelled as a sequestrum, while in a tooth we find gradual absorption of only the root. It starts at the apex, soon involves the dentin, and makes rapid progress between the lamellæ of the cementum, and at the dento-cemental junction. After a certain amount of the apex of the tooth has disappeared, we can easily diagnose the condition by means of the Roentgen method.

Hypercementosis. The fibers and cells of the peridental membrane have a wonderful resistance to disease. The cementoblasts very often remain vital, and are stimulated to activity by the irritating influence of chronic inflammation. This may result in the formation, layer upon layer, of new cementum, which causes a considerable enlargement of the contour of the apex of the tooth. Even after a considerable portion of the cementum and dentin have been destroyed, we may get new formation of cementum, and in sections we often find evidences of large absorbed areas extending deep into the dentin, and filled in with new cementum. Cementum may even be found completely lining the inner surface of the root-canal, as seen in one of the illustrations.

43 BAY STATE ROAD.

Electrobiolytic Theory of Dental Caries :

Observations on the Presence of Galvanic Phenomena in the Mouth ; with an Annotated Commentary on Related Topics.

By PAUL R. MANNING, D.M.D., Springfield, Mass.

THE relation of electro-activity to physiologic processes is food for conjecture and the source of fruitful experiment. Evidence of the production and effect of electric currents in the course of physiologic function, and consequent upon injury and disease, has been deeply studied. The existence of differences of potential in injured parts has been demonstrated in the experiments of DuBois-Reymond (1843)¹ and others. It is interesting to note that while caries of the teeth has brought about all manner of speculation through the ages, and, in the period of a generation, much scientific investigation, all of which has been embodied in a number of careful summaries,² there has been no weight attached to evidences of profound electro-activity in the mouth amid approximately perfect conditions for its maintenance.

EVIDENCE OF ELECTRO-ACTIVITY IN THE MOUTH.

Nearly every observer is familiar with "shock" produced by metallic intrusion

upon fillings under examination, the most common manifestation of galvanism met with in the mouth. Expressed in terms common in the usage of physiologic research, such a current appears tremendous, but its chief significance is in its indication of the electrolytic qualities of the saliva.³ There is evidence, however, that the presence of a foreign dissimilar metal is not an essential to the institution of galvanism and resultant electrolysis in the mouth. Essig⁴ noted that the presence of a silver band about

³ *Electrolytes*. It is generally accepted as probable that when certain substances are placed in solution their molecules undergo dissociation. The two or more parts are called ions. The completeness of dissociation and possible regrouping is, roundly speaking, in direct ratio with the amount of dilution of the solution. Such substances are called electrolytes in distinction from some others which do not undergo dissociation when in solution. The ions are supposed to undergo a definite regrouping in transitory paths, carrying with them the electrical charge—negative or positive—peculiar to them as ions. In the light of consideration of osmotic pressures, which is a necessary matter in dealing with dental structure, this principle attains very considerable importance, as an ion must be credited with as much osmotic pressure as a molecule. The saliva being a solution of electrolytes, it follows that the osmotic pressure will increase in the mouth in just that proportion to which the suspended electrolytes are dissociated. (Acids, bases, salts, and certain other substances under some conditions become ionized, *i.e.* they are electrolytes.)

⁴ Essig, "American Text-book of Prosthetic Dentistry." 1907. "... was probably due to galvanic action between the silver support and the tooth structure."

¹ "Untersuchungen über thierische Elektrizität," DuBois-Reymond, 1848-1860. Investigation of the "demarcation current" or current of injury. The cut end of a muscle is electro-negative as related to the lateral uninjured surface.

² "The Etiology of Dental Caries." Kirk, DENTAL COSMOS, 1914. This may not have been intended as a summary by its writer, but is probably the most excellent review up to that time, as well as presenting original views fully on a par with earlier work. (See also Cook and Johnson, in "Johnson's Text-book of Operative Dentistry.")

a tooth caused erosion of adjacent tooth structure, and he inferred that galvanism was the responsible force, although it seems he offered no explanation of the polar quality which must have been exhibited by the tooth structure, holding it to be self-apparent. In his observation is the essence, unstated, of the hypothesis which both concedes and overthrows some of the older theories of dental caries.

In 1912 the writer observed a case similar to that described by Essig. Since then a difference in potential has been recognized in mouths where caries is active, but where no foreign bodies are present. This current was determined experimentally by means of the capillary electrometer,⁵ and with its detection came the promulgation of the hypothesis that as there is in mouths where active caries is present a noticeable difference of potential, there is a consequent electrolysis, and an action in progress upon the polar electrodes. The factors which determine the constancy of the presence and strength of the phenomenon are not concerned in recognition of the principles at work.

FACTORS IN THE INSTITUTION OR MODIFICATION OF ELECTROLYSIS IN THE MOUTH.

Under detailed consideration of the passage of such a current, whether a tooth⁶ is to be regarded as a whole as a positive pole (as its elements would indeed indicate it to be), whether the enamel is to be considered slightly more positive than the adjacent dentin through

a fissure or an abrasion, or the cementum slightly more negative than either, or *vice versa*, the point remains that there is in progress an electrobiolytic action very largely responsive to obscure variations in mouth conditions.

The views held in the light of modern scientific philosophy relating to osmotic pressure,⁷ and ultimate diffusion against odds under prolonged sustenance of pressure, appear to coincide with the theory held regarding a constant action, however nearly infinitesimal, long continued.

The presence of galvanism holds still further significance when we consider the remarkable activity of colloidal substances in acidulated media, and the probable relation of the theory properly ascribed to Miller dealing with the activity of acids in caries to the principles of electrolysis and osmosis. It has many times been contended, even in the same discourse that lauded the work of Miller as a possible answer to the whole question, that his theories left something to be desired, and indeed it is a too improbable idea that the action of the mouth fluids alone might cause disintegration of the teeth. While the work of Miller and that of Michaels remains incontestable as to its actual data, it is in theorizing and the hope of discovering some one cause that there appeared an error, or at least a disposition to advance ideas not easily acceptable. Miller expressed in his later papers—before his death in 1907 he appeared to embrace

⁵ A combination in circuit of a vertical glass tube drawn into a fine capillary and holding mercury, the lower end of the tube supported in a sulfuric acid (dil.) bath in the bottom of which vessel is a layer of mercury. The mercury is put in circuit through the sides of the two containers with the articles whose difference of potential is to be noted, and a microscope used to note the fluctuations. The mercury in the capillary moves in the direction of the current upon momentary contact. The string-galvanometer would probably be a preferable instrument, but the writer had none at his disposal.

⁶ The cations are H, Na, K, Ca, Mg.

⁷ See footnote 3. It may be mentioned that it appears that substances which exert a definite osmotic pressure when in the body exhibit no such property when isolated, and Reid (*Journal of Physiology*, 1905) supposes that in the body proteins are closely allied with certain other unknown substances whose nature is either so obscure or so delicate that any attempt to isolate them would necessarily change their nature, and which themselves are indiffusible, but which, when existing normally with the proteins, render both capable of exerting feeble osmotic pressure. This is interesting to us chiefly because it shows the utter difficulty of setting up experimentally conditions similar to those in the mouth with any degree of surety of reproduction.

his theories for a time as proved—his belief in a course of operation of the features of the process of decay which entirely harmonizes with the theory under discussion, and these are the most rational of his papers, as it is possible to gain from them the clearest picture of an experienced practitioner's idea of dental caries, separate from his unproved theories. To Kirk,⁸ writing in the DENTAL COSMOS for January 1914, page 11, it was apparent that it was necessary to consider the etiology of caries "from a different angle of view from that which has characterized our mental attitude ever since the disease has been seriously studied at all." That the influence of secretions of the ductless glands has a profound effect upon the body metabolism is synonymous with the statement that they exert also a subtle influence upon the electrolytic qualities of the saliva—which, however changeable, are ever present—and possibly an effect upon the teeth as electrodes.

In writing at that time Dr. Kirk appeared to find a reasonable position, and gave due credit for the valuable work hitherto done to discover causative factors, and his article practically summarized the ideas of value that had been put forth at that time. That much definite knowledge has been accumulated as to mouth conditions is a necessary point to bear in mind in the formulation of any explanation dependent upon new data.

There are no important difficulties in the advancement of the electrobiolytic theory of dental caries. Undoubtedly chemic and biochemic phenomena are advanced by the electrolytic changes that are constant in the presence of caries. It appears probable that in the light of peculiar conditions affecting the quality of the electrolyte, chemical factors will modify the operation of electrolytic changes in the mouth.

POSSIBLE COURSE OF THE PROCESS OF ELECTROLYSIS IN THE MOUTH.

The ultimate definition of the status of the tooth structures in setting up different potentials, the location of the polar

charges, and the profound effect of the constituency as well as the reaction of the saliva on the presence and strength of electrolytic action, are points to be worked out. The early work of Jenner and of Pasteur is none the less logical on account of the exceedingly complex occupations and researches that have grown out of the older clinical work. The relation of the presence of various types of caries to further progress of electrolysis and the tendencies toward polarization,⁹ and the destruction of the poles as such through loss of their mineral content and the remainder of the end-products¹⁰ of the process are under consideration.

Finally, among modifying factors study is being made of the influence of foreign bodies in the mouth—fillings, etc.—and of the possibilities of the introduction of correcting and nullifying measures¹¹ for the attenuation and oblit-

⁹ The presence of a solution of one of its salts about the location of an electrode makes it non-polarizable, and it will be seen that this means of upsetting electrolysis in the mouth must be discarded, and the feature regarded as one disposing the scene to greater activity.

¹⁰ The work being done on the actual end-products of the process of electrolysis in the mouth, and the nature of the matrix of cavity decay as refuse from the process, promises to be interesting in its results.

¹¹ In connection with this theme Dr. Kirk referred the writer to the related literature "growing out of the warfare which was waged by the so-called New-departurists in the late seventies of the nineteenth century, the chief exponent of the electrolytic theory at that time being Dr. S. B. Palmer of Syracuse," and directed attention "to the Transactions of the Odontological Society of Pennsylvania for 1879 (published in the DENTAL COSMOS for 1879, page 623, and 1883, page 86), containing material by Bonwill, Register, Essig, Jack, and others."

These pages are of great interest in that they indicate the probable value of clinical observation in the institution of a state which we may term insulation, and show the importance of consideration of all chance data for the possible determination of measures which will affect the process of electrolytic decomposition in the mouth.

Dr. Kirk's communication is quoted fur-

⁸ See footnote 2.

eration of differences of electrical potential.

It is gratifying that the evidence in connection with this theory bears out the work of those advocates of the preparation of all tooth surfaces to a condition of irreproachable smoothness. This, it will be noted, is the condition of an inefficient electrode, and as we may never be able to obtain under the complex mouth conditions a state of polarization,

ther: "These references deal especially with the galvanic relations of gold or amalgam when in contact as fillings in the same or adjoining teeth. You may be interested in two personal observations relating to that matter. About 1882 or '83 I had occasion to examine the mouth of a woman who had applied to me for dental service, and I found very extensive amalgam fillings inserted on the approximal surfaces of her upper first and second molars in contact with large occlusal fillings of gold in the same teeth. The approximal cavities had been originally filled with gold, but recurrent decay had loosened the approximal fillings, which had been replaced by amalgam without disturbing the gold fillings in the occlusal surfaces. Extensive recession of the gum from gingival disease had occurred, and the amalgam reached almost to the bifurcation of the roots of the teeth. The margins were, however, absolutely perfect, and the fillings quite black. Nevertheless the entire operation was manifestly preserving the teeth, as the patient told me that the fillings had been inserted by the late Prof. James E. Garretson some fifteen years previously.

"As the combination of gold and amalgam in the same tooth in that way was at that time under serious condemnation by the best operators, I was struck by the success which had attended the use of amalgam and gold in this particular case, and was led thereafter to adopt the same method in similar cases, with equally good results. An interesting point in regard to the matter is that in all cases where the amalgam seemed to completely arrest recurrent decay its exposed surface quickly became quite black, so that the amalgam filling looked like an inlay of lignite or some other similar black material. In a few instances where the surface of the amalgam remained bright it became rapidly eroded, a condition which I attributed to the difference in salivary composition, the actual difference being that the saliva in these latter cases was found to be acid.

It appears probable that this measure will for all time constitute our sole preparation of the teeth to simulate a state of electrolytic inefficiency and consequent inactivity as electrodes.

The opportunities to explain in a reasonable manner all the known features of our clinical work dealing with caries and our accumulated knowledge of mouth conditions in their bearing upon the process of caries in alignment with

"The other case occurred in the practice of the late Dr. Isaac S. Fogg, with whom I was for a number of years associated as a partner. He had as a patient a lady of refined tastes and large wealth who when she first came to him as a patient had a lower left molar filled on its occlusal surface with amalgam, which had turned black. This filling was the only one in that particular tooth. The rest of her teeth so far as they needed it were filled with gold. On several occasions this patient objected strenuously to the rather unsightly appearance of the dark amalgam surface, and requested Dr. Fogg to remove the amalgam and replace it by a gold filling. This he was reluctant to do, because the amalgam, which was well finished, was perfectly preserving the tooth. However, the patient still insisting, he acceded to her request, but compromised by cutting out about half of the amalgam filling, making a cavity of sufficient depth to hold a superimposed layer of gold. The operation was completed and thus consisted of a composite filling the under portion of which was amalgam and the exposed portion gold. The operation was finished in the late afternoon. The next morning the patient returned with a history of intolerable pain of a peculiar character, which from her description evidently arose from an irritated pulp from galvanic shock. I was called in consultation by my partner, and mainly for the purpose of testing the galvanic theory I suggested that a small hole be drilled through the center of the gold filling, the hole to be filled with amalgam so as to bring the two metals to the surface exposed to the action of the mouth fluids, my thought being that I would thus be able to switch the galvanic circuit from the pulp and confine it to the two metals. The procedure was carried out, and the moment that contact with the oral fluids was established with the amalgam through the hole drilled through the gold filling as above indicated, the pain ceased and did not return again."

this theory are numberless,¹² and many must be left to further meditation and resolution to work out accurately those questions which the operation of these principles will bring to the minds of all observers.

If we consider a schematic case in which are existent all the hitherto supposed predisposing causes of caries, the presence of acids, bacterial growth, colloidal deposits (gelatinous plaques), mycoid fermentation, various forms of systemic disease and altered body metabolism, the peculiar deviations in the functioning of the ductless glands, or any of the perplexing forms of caries where there is no apparent cause aside from that under chief consideration, and where the mouth is kept scrupulously clean by every known artificial measure—that case will show the presence of differences of electrical potential; and

¹² It would appear that the enamel, having 97 per cent. of earthy material, on account of its greater compactness offers greater resistance to electrolytic forces than the dentin, with 72 per cent. earthy material.

whether that alone is the causative agent (and its strength in some observed cases indicates that it well may be), or merely the correlative of other factors, it is not the task of a moment to discover.

It is not difficult to recognize that the definite laws of the behavior of electrical phenomena which are in operation in the mouth may offer a groundwork for investigation of those forces which, beset on every hand by modifiers which approach in complexity the secret of life itself, split up the normal tissues of the mouth.

It becomes necessary to investigate every chance means of elimination of an influence which, though at nearly all times bordering upon the infinitesimal, becomes by its cumulative effect a menace to the preservation of the teeth; and in the solution of its elimination is the hope of salvage of the teeth. The means will be simple, and the recognition of a means to alter this influence will bring benefit to the individual not so much as to the race.

387 MAIN ST.

Logical Asepsis in Dental Practice.

By J. R. CALLAHAN, D.D.S., Cincinnati, Ohio.

(Read before the Dental Society of the State of New York, at its annual meeting, Rochester, May 10-12, 1917.)

“THE public advocacy of advanced ideas demands endless reiteration. The repetition must be so continuous, if possible varied, and long-maintained, that at last by the action of certain psychological sequences people begin to suppose that these ideas and arguments are their own, and that the advocate is a platitudinarian. It is only when, having long thought him mad, they think him dull, that he may congratulate himself on having done his work.”⁽¹⁾

I would be surprised if any member of this society should raise his voice in condemnation of the practice of logical asepsis in relation to any and every operation within the oral cavity; still I should meet with a surprise—no, two!—if 50 per cent. of those present do go through with a root-canal treatment and filling, maintaining a thorough asepsis, at the same time preserving the integrity of the surrounding vital tissues, with the methods and appliances now in use in the majority of offices.

I am not trying to hold my profession up to ridicule, for the dentist is as conscientious, capable, and thorough in his sterilization and general asepsis as other sections of medicine, excepting surgery; surgical practice stands upon asepsis as upon a rock, and it is for us to “observe, reflect, and record.”

I do not call to mind a single operation in daily practice that does not call for surgical cleanliness. At the same time I remember the scores of offices that I have visited; and when I examine the

various office appliances and equipments that are placed on exhibition by dental supply dealers—and above all, when I remove the veil from my own eyes, or have it removed through the experience and observations of two years’ service in and about the surgical pavilion of a large hospital, and study my own office and practice—I have to admit that we have not kept pace with the growth and development of aseptic surgery.

S. Mark White, M.D., University of Minnesota, in a paper read during the Panama-Pacific Congress in San Francisco, said: “For the most part dental asepsis has not yet reached the perfection of the surgical operating rooms; it becomes apparent that the methods used are such as to invite rather than prevent infection. This is a question, however, for the dentist.”

Again does another branch of the medical profession give us a truth that cannot be passed over lightly. Practically the same statement has been made over and over again by dentists, but do we as a profession make a whole-hearted effort to meet the situation? Suppose we examine our equipment and technique. With your consent let us analyze my own office and methods—for I myself have come up through all the phases of dental practice since 1877, and I have had, and still have, many things to learn.

In my own operating room the varnished walls are washed down once every week; the furniture is kept comparatively clean and free from dust; the linoleum floor is mopped every morning; no uphol-

stery on chair: on the floor will be noticed a rug (Fig. 1), and at the windows two heavy curtains.

BACTERIOLOGIC TESTS OF OFFICE CONDITIONS.

To test conditions, a culture-plate was placed on the cabinet and exposed for

What is wrong with these operating rooms from an aseptic standpoint? We come abruptly to the only point that we are now interested in: More dust gets into this room than should; the air of Cincinnati is dust-laden; there is the sweeping and moving about of the rugs, the shaking of the window curtains, the cleaning and dusting of the adjoining

FIG. 1.

ten minutes, then sealed and placed in an incubator. After 24 hours in the incubator, a smear showed the presence of a surprisingly large number (Fig. 2) of staphylococci. A further study of this culture-plate shows the presence of other micro-organisms; but just now we are interested merely in the presence of the pathogenic germs, or micro-organisms that we know may become disease-producing.

reception room (the books in the library being wonderful dust-catchers). If the rugs and curtains are removed, I believe this operating room can be kept sufficiently clean and free from dust to make it a reasonably safe dental operating room; notwithstanding this belief, the room is to be enlarged and remodeled.

Aseptic surgery is an impossibility unless the hands of the operator are surgically clean. To make the skin

absolutely free of micro-organisms by scrubbing is said to be an impossibility, therefore the surgeon makes use of

after 24 hours' incubation, staphylococci in abundance. (Fig. 3.) We will not stop to search for a stray streptococcus

FIG. 2.

FIG. 3.

thin rubber gloves. I think the time will come when the dentist will make more frequent use of gloves for his own protection as well as that of the patient.

or pneumococcus or any other stranger that might be on the slide. Then the hands were scrubbed with soap and brush in running hot water; again finger-prints

FIG. 4.

FIG. 5.

The following experiment may be of interest at this point.

Just before washing the hands the finger-tips were placed in contact with agar in a Petri dish; the slide shows,

were made in agar, and a smear shows a few big fat staphylococci. (Fig. 4.) The large size indicates a low virulence according to some authorities. The hands were again thoroughly sterilized,

and after working for a patient for fifteen minutes, finger-prints were made in agar: after 24 hours' incubation at $37\frac{1}{2}^{\circ}$ C. the smear showed a mixed culture of staphylococcus, colon bacillus, hay bacillus, etc. (Fig. 5.)

These simple and by no means thoroughly worked-out experiments show us that the rational thing to do is to get the hands clean and keep them clean, by thorough scrubbing for each patient, then rinse the hands at frequent intervals in some reliable non-irritating antiseptic—my choice being lysol or Dakin's fluid—or cover the hands with tincture of green soap, which soon dries leaving an invisible smear of soap over the hands that covers the sweat-glands, the hair follicles, and the epithelial scales, for a short time at least.

What appliances have we that should be sterilized, and how shall we sterilize them? Rubber dam is sterilized when in position on the teeth by washing the field of operation with alcohol (70 per cent.) or tincture of iodine. The chip-blower or hot-air pipe should be flamed; hand-pieces should be boiled in a green soap solution occasionally. For purposes of sterilization we may separate our instruments into two divisions:

First Division.

| | |
|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------|
| Clamps, | } These can be sterilized by boiling in water and soda in any receptacle that will hold water and stand sufficient heat: then dried on napkin. |
| Forceps. | |
| Broaches, | |
| Sprays, | |
| Hypodermic syringes, | |
| Mirrors, | |
| All cutting instruments, | |
| Pluggers. | |

Second Division.

| | |
|-------------------------------------|---------------------------------------------------------------------|
| Threads, | } These should be sterilized in flowing steam and dried in hot air. |
| Cotton pellets, | |
| Napkins, gauze, etc., | |
| Cotton on broaches, | |
| Absorbent paper points, | |
| Cotton shreds for packing in roots, | |
| Gutta-percha points, | |
| Pads, cottonoid, etc. | |

If it be true that the grade of service a dentist renders can be judged by the instruments or appliances he uses for a given purpose, then the sterilizers for instruments and materials that are used

in daily practice in most of the dental offices of this country indicate a low grade of service, so far as asepsis goes. We are not referring to any other feature of practice, simply to *asepsis* in all that the word means to any and every branch of surgery.

When the manufacturers realized that there was to be a demand for sterilizers, they began to put on the market sterilizers that would sell—not apparatus that would meet the requirements; and the majority of dentists permitted talkative salesmen to deceive them in a manner that would be amusing if it were not so serious. As a result, wall cabinets appeared in many offices, the glass doors of which bear the legend, in large gilt letters, STERILIZER. So loud and so positive is the statement that one is deeply impressed. How could a micro-organism dare remain in an office with such a menace staring him in the face! An examination of the interior of the cabinet, however, puts a microbe at ease. While the cabinet is new, a little formalin in some form is kept in the cabinet. Dependence is placed upon formaldehyd—which, as everybody knows, is a germicide of the first class, but it is a difficult matter to confine gas; it leaks out while the case is closed, and when the doors are open it *flies* out. If instruments are boiled, then dried on sterile towels before being placed in the gilt-lettered cabinet; if the gilt-lettered door is gas-tight, and there be formaldehyd in sufficient quantity within the gilded case, then the instruments will remain sterile so long as the gilt letters and the gas hold out.

CHARACTER AND DEGREE OF HEAT NECESSARY FOR STERILIZING INSTRUMENTS.

It should be remembered in this connection that "Formaldehyd is an effective germicide only in the presence of moisture. Room or chamber humidity should not be lower than 60 per cent., temperature not less than 16° C. Dry heat is much less effective as a germicide than steam. In a dry atmosphere temperature ranging from 140° C. to 180° C. must be employed to insure sterilization.

If steam under pressure be used, as in the autoclave, exposure for fifteen minutes to a temperature of 125°C . is sufficient to kill all known microbes. The difference between moist and dry heat doubtless depends upon the fact that the

Is it rational to claim that every instrument in the operating room should be sterilized? I do not see how we can in any reasonable way avoid doing so. Our hands and our instruments are in contact with infected tissues every day.

FIG. 6.

FIG. 8.

chemical or physical changes that cause coagulation of protein or the death of protoplasm take place, like such actions generally, more readily in the presence of water.”⁽²⁾ With regard to the *staphylococcus aureus*, Goadby (“Mycology of the Mouth”) says the thermal

I am not forgetting the difference between invasion and infection.

FIG. 9.

death-point of this organism is between 56° and 58°C ., for ten minutes' exposure, when in a moist condition; when dry, however, a temperature of 90° to 100°C ., acting for the same length of time, is required.

general nervous breakdown. The tooth was extracted, and a culture taken from the socket under proper sterile conditions shows the presence of an abundance of *streptococcus viridans*. (Fig. 7.) What should be done with every instrument

that was used? Should these instruments be placed in the case after an indifferent rubbing or washing?

CASE II. (See Fig. 8.) After the removal of the bridge and the impacted cuspid, streptococcus pyogenes, also S.

FIG. 10.

longus, were found in abundance. (Fig. 9.) Should these instruments be sterilized?

CASE III. (See Fig. 10.) A case of arthritis. This root has been filled with a dollar per bottle root-filling compound, warranted to prevent infection or rein-

FIG. 11.

fection in any root for a lifetime. A culture was taken from a broach that was in use while removing this popular and widely advertised root "stuffing" (Fig. 11), and shows the presence of almost every species of bacteria known to science. If any instrument used in

this case, up to the time of filling the canal, should be laid on the cabinet or desk, the whole office would be liable to infection. What is the logical thing to do with these instruments?

FIG. 12.

FIG. 13.

CLASSIFICATION OF INSTRUMENTS FOR STERILIZATION.

I have given above in the first division the list of instruments that could be sterilized in a most satisfactory manner by boiling in water. No sterilizer is really necessary for these other than a metal pan over a fire; some simply to be held in the alcohol flame. The second

division, however, requires something different; they should be thoroughly sterilized and should come to the chair perfectly dry and cool, without having been touched or exposed to the chance of infection by being brought in contact with napkins taken from a dusty drawer.

Japanese paper canal points as they come to us in the sealed package are sterile, but the package has to be opened, and they are mussed to some extent before being used, some being kept for some time before being required for use.

A few of these points were passed quickly from the box to a Petri dish and then incubated. (Figs. 12 and 13.)

but suppose a mild antiseptic is being used—or, more to the point, suppose the cotton is being used to absorb blood or moisture—would it not be far more logical to sterilize the cotton, without using drugs with it, *after twisting* the cotton on the broach?

Fig. 14 shows cotton twisted with clean hands on sterile wood points (steel broaches rust in incubators), then placed on agar media in a Petri dish, and after 24 hours' incubation produced a growth of hay bacillus and colon bacillus in streptococcus form. (Fig. 15.)

We have seen that there are several ways in which to sterilize the various

FIG. 14.

FIG. 15.

These showed what are commonly called hay bacilli or *B. subtilis*; colon bacilli are also plainly seen in the center. The logical thing to do is to sterilize every point just before using.

This picture (Fig. 14) illustrates the most asinine habit that any group of specialists ever permitted themselves to become wedded to, namely, the twisting of cotton on broaches with the bare fingers, then thrusting that infected cotton into a deep canal from which they are trying to remove every trace of infected, or liable to be infected, material. If the cotton is saturated with a powerful germicide and you want a powerful germicide in the canal, all well and good;

instruments, but the one best method for sterilizing any and all dental appliances is flowing steam, combined with hot air for drying. The steel instruments, the paper points, the gutta-percha points, the napkins, everything to be sterilized, can be taken care of in the best and most thorough manner known, all at one time, in the same sterilizer.

Fig. 16 shows two sterilizers, and a still for distilling water. The small sterilizer is simply a boiler that is used for steel instruments. We do not really need the boiler, because the steam-chest or the Rochester combination sterilizer does everything, and does it better than any appliance that has come to my no-

rice. Having worn out three electrical heaters, I am prepared to say that a gas heater is much more satisfactory, especially if you have a pilot light as shown in the illustration. The pilot is lighted the first thing in the morning, is always ready, and keeps the water warm. By

FIG. 16.

turning on the gas in the main burner, steam is produced in a very few minutes. The plan of the boiler is shown in Fig. 17. The water being in the lower chamber, the steam passes up around and into the main chamber when desired. After having steamed the contents of the upper basket, a turn of the lever near the top allows the steam to pass out without entering the sterilizing chamber where the

contents, gauze, cotton, etc., become dry in a few minutes. This outfit is only about half as large as it should be. The inside measurement is 7 x 14 inches. This sterilizer is to be found in all surgical and many dental supply houses, and as a rule they try to sell the smaller size, which I have found to be too small. If I can prevail upon you to avoid the im-

FIG. 17.

possible little toy sterilizers so popular today, logical asepsis in dental practice will have made a step forward.

Movement of Teeth Predetermined by Engineering Instruments: Appliances Designed in Accordance with Analytical Mechanics.

By FREDERICK LESTER STANTON, D.D.S., New York, N. Y.

(Read before the annual meeting of the Eastern Association of Graduates of the Angle School of Orthodontia, New York, May 7 and 8, 1917.)

[Copyright 1918.]

"What a man feels intensely, he struggles to speak out of him, to see represented before him in visual shape."

"We can see with the perception of truth is joined the desire that it thus shall prevail."
—CARLYLE.

FROM the fall of 1914 to the early spring of 1915, the author spent most of his working hours in making maps of dentures. Models of malocclusion were mapped by means of dividers; bisecting lines were made to locate the various points of interest. It seemed to the author at that time that the mapping process would solve many of the mooted questions of orthodontia. Orthodontic specialists were invited to his office to inspect the work, but little or no interest was shown. The writer, finding no way to map by hand the relative heights of the teeth, sought advice. The *Scientific American* offices and various instrument houses were visited. Finally a mechanical engineer, Mr. Hanau, said he could construct an instrument to record the relative heights of the teeth. This instrument was so designed as to make the maps previously drawn by hand, as well as record the relative heights of the teeth.

Mr. Hanau became interested in this work and the data I had collected from the examination of skulls in the National Museum, and said he could find a mathematical formula for arch pre-determination.

The surveying apparatus was shown at the annual meeting of the Connecticut State Dental Association in 1915.

FIG. 1.

and a summary of the investigation was given before this society in May 1915, but scarcely any discussion was evoked.

A paper on this subject was sent to the Panama-Pacific Dental Congress held in San Francisco, Cal., September 1915, the major part of which was written by Mr. Hanau, and described his method of

Toward the close of 1915 the possibility of finding a formula for occlusion seemed to the writer so remote, and the estimated amount of money necessary for the investigation so large, that he decided to consult the Engineering department of Columbia University to see if the investigation he had undertaken was proceeding along the best lines.

FIG. 2.

Oculusal view of models shown in Fig. 1.

predetermining the occlusal arch. This method of trial on the drawing-board consists of laying off on various curves—parabolas, ellipses, etc.—the mesio-distal diameters of the teeth until the true occlusal arch for a given case is found. The paper referred to remains unpublished, as the proceedings of the Congress have not appeared. Although *Dental Items of Interest* advertised this paper as one that would appear in that journal, it was finally rejected by the editor.

It was found that at this period—after the maps had been made and the tooth widths measured—it would take the engineer more than twenty hours to complete the book of plans for a case, and that some cases would require an expenditure of as much as \$150 for the engineer's time.

After a short consultation with Professor Finch of Columbia University, he said he saw no great difficulty in the problem, and suggested Gilbert D. Fish,

C.E., to assist me in the investigation. You can imagine my surprise when Mr.

sultation, during which I described to him the conditions of normal occlusion,

I selected for trial the model which had given the greatest amount of trouble in

selecting the proper occlusal arch by the use of mathematical curves.

At the end of two weeks Mr. Fish returned with the correct arch form predetermined, *i.e.* it was like the one so laboriously formed by the method of trial of Mr. Hanau. Mr. Fish also devised a mathematical formula and method of arch predetermination which

models of practical cases, the book of plans showing the predetermined movements, the progress surveys showing the relative movements accomplished, and the appliances used. I shall not attempt to describe the mechanical principles involved in the selection of arch forms, as that phase of the subject was ably pre-

FIG. 9.

FIG. 10.

Occlusal view of models shown in Fig. 8.

was incorporated in an original paper. This paper was sent to the editor of the *DENTAL COSMOS*, who finally returned it as not available for publication. Mr. Fish stated that arch predetermination was not a mathematical problem but a mechanical one, and he presented me with the arch-determining instrument, the oclusograph.

I shall not take your time in describing this method, as you may better read it in an article to be published shortly in the *International Journal of Orthodontia*, by Mr. Fish, but shall show you

sent to you by Mr. Fish in his paper yesterday.*

In addition to the foregoing I have decided to speak about arch predetermination, especially after the paper of yesterday by Dr. Hellman, and so I have incorporated a few slides.

You remember it was said yesterday by Dr. Hellman that the teeth varied in

size, although large teeth might be found in narrow arches. We have been

endeavoring to tell you in the short papers we have written on this subject that the *whole arch depends on the interrelation of the sizes of all the teeth, all*

FIG. 14.

dimensions of the teeth, and all parts and forms of them. If you should have in two cases the same teeth, the only exceptions being in the two incisors, and they should vary only two millimeters,

FIG. 15.

Progress survey of models in Figs. 8 and 10. Compare this map with the original malocclusion, Fig. 11, and the proposed occlusion, Fig. 12.

the entire arch would vary. The smallest change in any tooth produces a material change in the arch form.

The common picture of malocclusion is a needed expansion of the lateral units.

We join the bicuspid with a yoke, and that unit must be moved from malocclusion to its predetermined occlusion.

The movement of the anterior portion of the arch is considered separately. In all cases of malocclusion the common picture is that both upper and lower cuspids need to be moved in this way. The distal corner travels much farther than the mesial.

FIG. 16.

The dental surveying apparatus. An engineering device used to orthographically project the denture.

I believe all the mistakes made in my orthodontic treatment in the past have been due to a lack of expansion in the bicuspid region, and a pulling on the incisors. I believe the incisors should not be banded except in rare cases, and their treatment should not be attempted until the form and dimensions of the arch have been obtained by moving the bicuspid and molars of both jaws to their true positions.

In the case of a mixed denture we set the instrument with the deciduous teeth

in occlusion, that is, the cuspid and two molars. We then insert a link the size of the permanent lower central. Knowing that the lower lateral has a quite constant relation to the lower central (it is about half a millimeter larger) we insert a link for the permanent lower lateral. After measuring many sets of teeth we found the ratio, between the combined widths of the four upper incisors and the combined widths of the four lower incisors and one cuspid, to vary from 100 to 110.

We now manipulate our instrument so as to keep occlusion of the deciduous

FIG. 17.

The occlusograph in this position shows the occlusion of the case represented.

teeth—molars and cuspids—and open a gap in the upper incisal region to permit four teeth to erupt whose combined diameters will give with the lower five teeth a ratio of 105—an average ratio. Having made this tentative treatment, we wait until all the permanent teeth are erupted, and then a revision of the arch is made as the permanent teeth erupt.

It seems better to put this tentative treatment on paper and examine it than to attempt to estimate by the eye and leave the mental diagnosis unrecorded. We can show the predetermined movements, and see how near they come to the plan. If they do come near the plan, then it would seem to be a rational treatment to use.

CONCLUSIONS.

(1) As long as orthodontic procedure consists in moving teeth by means of appliances, a knowledge of analytical mechanics is essential for the intelligent designing of an appliance.

(2) As long as orthodontia has for its goal normal occlusion, the operator should know the form and dimensions of the occlusal arch of each case before beginning treatment.

(3) If any other goal than normal occlusion is the aim of an orthodontist, *that* arrangement of the teeth can and should be mapped out in advance of treatment, and the relative movements of all teeth predetermined.

(4) Until the etiology of malocclusion is known and its prevention is accom-

plished, the vast bulk of orthodontia must be done *for the masses by the general dentist*.

(5) Safe and sane orthodontia can be accomplished by the general practitioner by means of predetermined movements combined with appliances selected with due regard to analytical mechanics.

(6) If the above conclusions are correct orthodontia will be brought within the reach of the masses; the general practitioner will be rendering a good service, and the orthodontic specialist will find his field enlarged, as many more will demand the services of the specialist.

Orthodontic Treatment of Advanced Cases, and Patients Coming from a Distance.

By J. A. CAMERON HOGGAN, D.D.S., L.D.S., Richmond, Va.

(Read before the Eastern Association of Graduates of the Angle School of Orthodontia, New York, N. Y., May 7, 1917.)

MR. CHAIRMAN AND GENTLEMEN:

IN this lecture, or presentation of slides, I will show you a model, and the means of constructing it, with which I hope to be able to get more than a simple register of the present position of the teeth, at the commencement of orthodontic treatment.

It has seemed to me that if it were possible to get a model that performed some other function than merely to register the malocclusion, a model that would extend the limitations of plaster of Paris, a model with a greater range of usefulness, a model that would give some knowledge of the teeth at any period of the treatment, then I should be bringing the science of orthodontia a

step nearer the desired goal. Further, I thought it might be possible to construct an appliance upon that model, by means of which someone other than the man who constructed the appliance could move the teeth. In the discussion this morning of that part of the President's address which refers to the possibility of having a dentist treat a case, or assist in the treatment, at some distance from an orthodontist, there arose one of the points that I wish to bring out in the use of this model.

DESCRIPTION OF ILLUSTRATIONS.

Fig. 1 is simply an illustration of a method of producing occlusion of teeth in an artificial way as I attempted to do

FIG. 1.

A

B

FIG. 2.

FIG. 3.

FIG. 4.

FIG. 5.

some years ago. It is merely a study of occlusion, and the bones of the face concerned in breathing. The whole model can be disarticulated, and I display it here to trace with you the influence upon

FIG. 6.

FIG. 7.

FIG. 8.

a mind working and playing with occlusion over a period of ten years.

In the construction of this model of the teeth in metal, I aimed at getting an individual wax impression of each tooth, and to do it I first took an impression in

the usual way with plaster of Paris, and with the impression in a more or less moist condition I dusted over it talcum powder with a camel's-hair brush, and forced softened inlay wax into each individual impression of the teeth.

Fig. 2. The illustration on the right shows the wax model after it is removed

FIG. 9.

from the tooth. That on the left shows the tooth after the wax had been carved away from the unexposed portion of the crown. My object is to get a wax model of the complete crown. The wax is not necessarily an exact duplicate of the unexposed portion of the tooth, but there is so little to carve that the portion which is carved and represents the complete

FIG. 10.

crown will be so nearly accurate that it serves the purpose, since it is below the contact point.

Fig. 3 is a picture of all the crowns of the teeth carved, cut off, and replaced in the impression.

Fig. 4 shows the wax models in place in the impression, attached by means of plaster of Paris on a camel's-hair brush, placed about the necks of the wax models

which have been carved. The object is to add to the impression that portion which has been added to the wax crown.

FIG. 11.

We now have the wax model covered up approximately to the point at which the cementum joins the enamel.

FIG. 12.

Fig. 5 is an illustration of a small oval post bar inserted here to show its construction.

FIG. 13.

Fig. 6. Having melted out the wax from the impression form, we have an impression of each individual tooth, into which is poured Melotte's metal, and while it is molten the little post is inserted to engage the metal. The cross-

bar is inserted in the metal to make the post stable. If there is not a satisfactory film of plaster between the teeth, fill the alternate tooth impression with moldine, pour one tooth at a time, then remove the moldine and paint the exposed metal of the adjacent teeth with a thin

FIG. 14.

coating of plaster, so that the new metal will not stick to them. Having poured the metal into each individual impression, paint the posts and exposed surfaces of the metal teeth with thin plaster, then pour a metal base to preserve the relation of the teeth to each other.

Fig. 7 shows a model the teeth of which are removable.

FIG. 15.

Fig. 8. An appliance has been made on this model.

Fig. 9 shows the upper and lower models in occlusion.

Fig. 10 is a lateral view of the same models.

Fig. 11 shows an arrangement of the teeth by taking them off their base, putting them in an articulator, and placing

them in the position into which I believe I shall necessarily have to move them to get normal occlusion.

Fig. 12 is a lateral view of the same case. The second molar was not constructed in this model.

Figs. 13, 14, 15 are models which represent the most desirable forms of malocclusion that I could obtain from a mutilated case. I have simply produced in an articulator the various possible combinations of the metal teeth, and chosen the best. There are mutilated cases in which I believe it would be impossible to establish normal occlusion. If it is inadvisable to reopen spaces to get what constitutes a normal occlusion, then what is the most desirable form of malocclusion? This enables you to make a study of what might be the most desirable form of malocclusion, and with this model you have a guide. Angle gave us a guide in the treatment of malocclusion, which guide was normal occlusion. This method of reproducing teeth in metal is a guide in those cases in which normal occlusion is impossible or inadvisable. These are usually mutilated cases and are few in number, but constitute the real test to the orthodontic specialist.

One of these models represents a construction from the impression sent to me by a dentist. I completed my metal model, made an appliance, and sent it to the dentist. He placed the appliance in position. I wrote my directions for treatment by him, and in two months' time he will send me another impression. I shall then take these teeth from that model and put them in the new im-

pression, form a new base and get the then present position of the teeth. I shall make a new appliance, send it to him and he will place it in position. In two months' time he will send me another impression and I shall repeat the operation, sending him an appliance that will fit that model and the mouth.

The question in my mind is whether I can treat a case of malocclusion correctly without seeing it. I have three cases which I am treating at the present time. I do not claim positively that it can be done, but I claim there is a possibility.

If there is any period of the treatment which is slow, tedious, and most difficult, it is the final settling down of the teeth after you have practically brought them into normal occlusion. I believe that if I make an appliance on that model with the teeth arranged in normal occlusion, I can get an appliance that will encourage those teeth to settle down more rapidly than they will in any other way. If there is any variation in teeth, as there is bound to be, and we make a set of these cast teeth and place them in an articulator and endeavor to get normal occlusion, we shall soon discover the anomalies and the difficulties involved in the case. In this particular instance (Figs. 11 and 12) I arranged the teeth several times in what was to me normal occlusion, and I always seemed to arrive at the same position in regard to the shape of the arch.

FIFTH AND FRANKLIN STS.

[See also *Discussion*, as reported under "Proceedings of Societies," this issue.]

Iodo-Glycerole.

By EUGENE S. TALBOT, M.D., D.D.S., Chicago, Ill.

FROM time to time there appears in dental journals and text-books my formula for "Iodo-glycerole," without giving me due credit. A certain professor in one of our large university dental schools, when lecturing upon the subject of so-called Pyorrhea, gives the prescription to the students as his own. Another professor has published the formula in his text-book as his own, and has given it to a commercial house under his name to manufacture and sell to the profession for gain, when it was given by me to the profession many years ago without money and without price.

My reason for this article is that the preparation is so efficient and is now almost universally used: if every writer on the subject of so-called pyorrhea mentions the prescription without due credit, the author's name will soon be forgotten in relation to it.

In 1878 the author first began to experiment with different drugs in connection with his researches upon "Interstitial Gingivitis and Pyorrhea Alveolaris." At that time he was getting splendid results with the official tincture of iodine. It was not entirely successful, for the reason that, when continued for a length of time, in some cases the mucous membrane became sore and the tissue was destroyed. Again, the tincture of iodine when in contact with the saliva would spread over the tissues of the mouth and was difficult to control. I wished to use an astringent to contract the gum tissues, and I found it impossible to use other drugs to dilute or strengthen the preparation and to make a clear solution. In

consulting my friend the late Professor Hallberg, dean of the School of Pharmacy of the University of Illinois, he suggested that, if glycerin was added, other drugs could be used and water be added to make any strength of solution required, and one unharmed to the tissues.

Iodin crystals and zinc iodine were used in place of the tincture containing the alcohol, and water could be added in any quantity to dilute the preparation to any strength.

The mixture of iodine and glycerin was first made by the author, in 1880, and was called "Iodo-glycerole." The use of glycerin, and glycerin only, allows all the preparations of iodine to be made into clear mixtures—which cannot be done without it.

Certain persons have added potassium iodide or other drugs, or a few drops more or less of water, in order to claim originality. When, therefore, a formula of iodine, no matter in what form, and glycerin, is used, to that formula should be added the name "Talbot."

I take it that every dental school in the country has a professor on "ethics," and that the dental graduate is as familiar with the ethics of his profession as the medical graduate. If, however, the professors in our schools ignore the rules of courtesy and ethics, we can hardly expect the dental graduates to do so. It is high time that dentists, if they desire to be known as a profession, should at least learn the "golden rule."

31 N. STATE ST.

A Dental Anomaly: Report of a Case of a Rudimentary Impacted Lower Third Molar.

By HARRY J. FELDMAN, D.D.S., First Lieut. D.R.C., U.S.A.,

DENTAL INTERN LINCOLN HOSPITAL, NEW YORK CITY.

A MALE patient, seventeen years of age, presented at the dental clinic of Lincoln Hospital with a large swelling in the region of the angle of the mandible, right side, with considerable trismus and glandular involvement.

The condition had commenced six weeks preceding his visit, and had been growing worse. During that time the patient had been to several dentists and physicians, and repeated incisions had been made in the lower right molar region and extra-orally at the angle of the jaw.

Upon examination the second molar was found to be very badly broken down, no third molar having yet erupted. The extra-oral incision was still suppurating, making it evident that nothing short of immediate treatment would halt the suppurative process and allow the patient to open the mouth.

The second molar, being the apparent cause, was promptly removed under mandibular anesthesia, induced by the aid of a mouth-gag. Before removing the tooth, considerable pus was evacuated by incising along the buccal fold.

Upon probing the alveolus of the second molar, however, it was noticed that there was no appreciable dissolution of bone—which surely ought to have occurred if the quantity of pus evacuated emanated from that source.

This led to an exploratory incision into

the third molar region and determined the presence of the cusps of an impacted third molar deeply embedded in the retro-molar fossa, pointing externally.

A flap of tissue was then elevated from the ramus and retracted by the nurse. After considerable chiseling and drilling the tooth was extracted. Upon first examination the tooth gave the appearance of having been broken off with the apices left in the ramus. What appeared for the moment to be a piece of hanging gum tissue, and which was hurriedly washed away to examine the tooth, proved to be the developmental sac, and the soft pulp tissue within the hollow unformed roots was the dental papilla.

Cases of this character, where early impaction prevents development and soon induces with it concomitant conditions such as suppuration, glandular involvement, and trismus, endanger the life of the patient, and point to the necessity for early procedure as a prophylactic measure against systemic infection and prove that too long waiting for suppuration and trismus to subside is contra-indicated. The mouth-gag should be employed at once in such cases to eliminate the possibility of trismus becoming worse.

As another prophylactic measure it may perhaps also be wise to radiograph the other third-molar areas and study their progress, as symmetrical occurrence is very probable.

CORRESPONDENCE

Sterilization of Tooth Tissues with Silver Nitrate.

TO THE EDITOR OF THE DENTAL COSMOS:

Sir,—The article entitled "A Method of Sterilizing, and at the Same Time Impregnating with a Metal, Affected Dental Tissue," by Percy R. Howe, A.B., D.D.S., in the September DENTAL COSMOS, I found to be extremely interesting. May I sound a word of warning, however, in regard to the use of silver nitrate in the roots of anterior teeth? I have several patients for whom I treated anterior roots, prepared for pivot crowns, with silver nitrate some ten years ago. Subsequently the gum tissues over the roots darkened as the result of the impregnation of the silver salt, causing a most

disagreeable impression, and for that reason I discontinued its use in these teeth. I have found silver nitrate very effective when applied to affected tooth tissues which are not exposed to light, as advised by Dr. Black, but even if applied only to the apical third of anterior roots, the danger of staining the crown of the tooth, with its attendant disastrous results from an esthetic point of view, more than offsets the benefits derived from its use in these places.

Very truly yours,

WM. H. NITZSCHKE, D.D.S.

RIO DE JANEIRO, BRAZIL.

Unclean Yet Sound Dentures.

TO THE EDITOR OF THE DENTAL COSMOS:

Sir,—Regarding the saying that "A clean tooth never decays," I would add "Neither does a dirty one, necessarily."

I recently spent practically a whole afternoon cleaning a set of thirty-two teeth, all perfect and in good occlusion, in a patient, a rather good-looking young woman just past thirty years of age. Tartar was present to such an extent that it formed almost a solid wall with vertical cracks to indicate the presence of

the teeth. The tip of the upper cuspid was all that showed on one side. The sulci of the molars on the right side, both upper and lower, were completely filled with tartar. The patient said she had showed them to a dentist once, and he looked "kinda funny." I presume he did!

Very truly yours,

F. A. GRAHAM, D.D.S.

HARBOR SPRINGS, MICH., October 6, 1917.

Dentistry as a Career.

TO THE EDITOR OF THE DENTAL COSMOS:

Sir,—I have before me a question to determine which I have often wondered how I should settle did it ever come to my lot to decide. It now appears in the form of the question of the career to advise for a *protégé* of mine, my young nephew, who is completing his academic education. By reason of his talents and personality I am convinced I should advocate for him either the profession of medicine or the profession of dentistry, in either of which I am satisfied he would make no small success, and one or the other of which he desires to take up. I have often wondered what would be the result if the average were struck from the sum of advice given by a representative number of dentists regarding such a matter. Would the nature of this average advice mean that dentistry as a factor for human good was a success or a failure? Would it mean that dentistry as a developer of character—taken in the broad sense—warranted the devoting of a life to it, rather than to the practice of medicine?

The following represents to my mind the way in which the successful dentist views his profession: He regards it as at present but a pioneer in the realms of public appreciation, recognition, and

human service. He believes that its possibilities as a healing art and science—not the “healing art”—are practically unlimited. He realizes that it is no longer but little more than a mechanical trade and only in theory a profession. But as he considers these facts his thoughts seem always to point toward the same idea, namely, that dentistry is a specialty of medicine practiced without the degree of Doctor of Medicine, unlike the other specialties of medicine. Now, if, as it appears by natural and logical reasoning, dentistry is to be eventually absorbed into medicine, should not the education of the future dentist be the same as that of the medical student, with an added year or two or more if necessary to obtain the requisite dental qualifications? Would this not at one stroke raise the status and broaden the usefulness of dentistry? Then why not so educate the coming generations for the practice of the specialty of dentistry? I think this is a question of sufficiently imminent import to warrant a very free and full discussion in the forum of our dental magazines.

Cordially yours,

WM. H. BARNHARD, D.D.S.

WASHINGTON, D. C.

PROCEEDINGS OF SOCIETIES

New Jersey State Dental Society.

Forty-seventh Annual Convention, held in Atlantic City, N. J., July 11 to 13, 1917.

WEDNESDAY—*Morning Session.*

THE forty-seventh annual meeting of the New Jersey State Dental Society was called to order at 10 A.M., on Wednesday, July 11, 1917, on Young's Million Dollar Pier, Atlantic City, N. J., by the president, Dr. James I. Woolverton.

The Rev. HENRY MERLE MELLE, Atlantic City, invoked divine blessings on the deliberations of the society.

The PRESIDENT, Mayor Bacharach of Atlantic City is absent from the city, and Mayor Harcourt of Longport will deliver the address of welcome.

Address of Welcome.

Mayor HARCOURT of Longport then addressed the society as follows:

Mr. President and members of the New Jersey State Dental Society,— Mayor Bacharach has requested me to come here and greet you this morning on behalf of Atlantic City. Mayor Bacharach would have been here; he is very faithful in the performance of his duties to the visitors and to the conventions which honor this city with their visits and who have contributed so much to make this the wonderful City by the Sea. But this time he is not with you because he has been called away to perform duties which are very burdensome, involving the mobilization of the military forces of the state and the preparations for the entrance of this state with the federal forces in the great conflict to make the world a

safe place for the great masses of its people, and a very unsafe place for a few of its people who would destroy the freedom of the masses. I believe you will forgive his absence this morning when I offer you these reasons.

The duty which every individual owes to this state and nation during these dark days has been quickly recognized, and, I am glad to tell you, unselfishly and patriotically performed, by the members of your profession and of this society, resident in this city and county.

An instance of this performance of duty on your part was on the formation in this city of a battery of artillery as a unit of the New Jersey regiment of artillery. Many of the men who came forward and offered themselves to the company were found to be defective because of bad teeth. Immediately the dentists of this city and county came forward and volunteered to give their time and service to these men, so that one of the most important parts of the fighting man would be sound and ready for the campaigns to come.

Men like you, who do these things quietly and without the blare of a brass band, are not often the recipients of medals nor are such acts often mentioned in the news of the day, but it is nevertheless a performance of duty and exhibition of sacrifice just as laudable and every bit as necessary for a successful and quick finish of this war in which physical science is playing such a large part, and divine science such a small part. Future

wars must be prevented by the scientific application and enforcement of the principle of right over wrong, but this war will be won by the nation most highly developed and organized in physical science; that nation will be the United States, and your profession is doing and will continue to do its part.

I present to you the key of Atlantic City. Henceforth the doors are wide open, but don't take them off the hinges, because when the time comes that people must leave us we always lock the doors again, so that you can have an excuse to prolong your stay. Your president has just told me that during the last two days no one has been getting to bed until four or five o'clock in the morning, and that he realizes that he is up against it until this convention closes. He feels his responsibility so keenly that I know this key will be in safe hands. Mr. President, I present to you the key of Atlantic City.

The PRESIDENT. I accept this key in the name of the New Jersey State Dental Society, and will see to it that the doors are kept open.

The Secretary proceeded to call the roll, whereupon Dr. MANNING moved that the roll-call be dispensed with. (Motion carried.)

The PRESIDENT. The secretary will read the minutes of the last meeting.

The Secretary proceeded to read the minutes of the last meeting, whereupon, on motion (as follows), further reading of the minutes was dispensed with.

Dr. FOWLER. Mr. President, I move that the printed minutes of the meeting, as printed in the official record, be accepted as the minutes of the meeting. (Motion carried.)

Dr. Asher S. Burton, vice-president, was called to the chair, while the president, Dr. WOOLVERTON, read his address, as follows:

President's Address.

By Dr. J. I. WOOLVERTON, Trenton, N. J.

You have honored me with the privilege of addressing you as president of the New Jersey State Dental Society, and of

bringing to your attention such matters as may be deemed of importance to the welfare of our society, by which it may maintain its position as a leader, not a follower, among dental societies.

To hold this place will even more in the future require that we use judgment in the selection of our officers. They must be men who are capable, willing to sacrifice themselves, and to devote the time that is necessary to carry on this work, not men who are seeking honors only.

During the past few years, owing to the increased demands for space necessary to accommodate the exhibits of the convention, there has been considerable difficulty in securing a place of sufficient size to house the entire meeting under one roof: in fact, last year it was necessary, as you know, to have the scientific meetings in a separate hall.

This year we were unable to secure the Casino in Asbury Park, where we held the last two conventions, forcing us to look for another place for the meeting of 1917.

In 1911 the Atlantic and Southern, and in 1912 the Atlantic, Southern, and Mercer societies held successful and well-attended meetings in Atlantic City. This was brought to the attention of the Board of Trustees, who, after some negotiation, have secured a favorable contract from this city.

This change has already proved beneficial from a financial standpoint, and the indications are that there will be no falling off in attendance. With such men as Drs. Price of Cleveland, Thoma of Boston, and Moffitt of Harrisburg, as essayists, and an excellent group of clinicians, this should be the most successful meeting the New Jersey State Dental Society has ever held.

An innovation in the management of the convention is being tried out this year in the appointment of a business manager, who has full control of the staging of the convention, relieving the chairman of the Exhibit Committee of a tremendous amount of detail work. This is working to such satisfaction that I would recommend the position be made permanent, that he be empowered to make all con-

tracts with the exhibitors and collect the moneys, with such other duties as may be directed by the Board of Trustees, and that he be compensated in a reasonable amount for such services.

DENTAL LEGISLATION.

The one hundred and forty-first session of the New Jersey Legislature passed no legislation affecting the law relating to the practice of dentistry, but has enacted a law directly affecting the appointment of members to the Board of Registration and Examination in Dentistry, in that it requires the society to name three dentists for each vacancy as it may occur, the Governor naming one for the position. This is sure to bring a certain amount of politics into the appointment, which is to be regretted. We must be more careful than ever in selecting men of high integrity and qualifications to fill these positions, to the end that the board may ever be an honor to the dental profession of New Jersey.

At the annual session of the society, a certain amount of business must be transacted; under the present plan every component society has a representative on the Board of Trustees, to bring the members in closer touch with the business of the society, and that the society may devote more time to the educational side of the convention; I would recommend that a complete record of the transactions at each meeting of the Board of Trustees be furnished them, to place before their local societies; also that the reports of the various committees—unless they contain matter to be discussed by the society—be read by title and printed in full in the *New Jersey Dental Journal*.

THE NEW JERSEY DENTAL JOURNAL.

This brings me to the *Journal*, whose staff is working for us every day in the year, and a good many nights until late, with no compensation whatever except our gratitude; let us show it by reading the *New Jersey Dental Journal*, if in no other way.

The history of the New Jersey State Dental Society is completed up to the

time of reorganization, and it is recommended that a committee of three be appointed to bring it up to date.

MEMBERSHIP.

Our membership, while increasing steadily, should have a much larger proportion of the dentists of New Jersey. We can get them if each one of you will make it your business to bring in one new member; and to assist in this I recommend that a director of membership be appointed to carry on the campaign, with the slogan—"One thousand members at our fiftieth anniversary in 1920."

The National Dental Association is now sending to each member monthly a journal which reports the findings of the Research Institute. These alone are worth many times the price of the magazine, and the value of this work not one of us can estimate. The Research Institute is now asking that we increase our dues \$1 per year for the support of this institution, and I most earnestly recommend that this be done.

THE PREPAREDNESS LEAGUE.

Of all the great events during the past year, the most important to us as a nation and professionally is the entrance of the United States into the European war. The national side needs no comment; we must win. Your Board of Trustees have taken such action as the conditions demand in the formation of the Preparedness League of the New Jersey State Dental Society, whose chairman will give a detailed report of the great work they have accomplished.

A portable motion-picture machine has been purchased that may be used in any place where the 110-volt current is available. This will be used at our state meetings, and will be loaned to the component societies who may wish to secure it. There are now nearly a dozen films available through the courtesy of the S. S. White Co., and many more that may be rented at a moderate figure. I would recommend that a committee of three be appointed to take charge of this machine and make arrangements for its use.

In conclusion, I wish to express my appreciation of the hearty support of the officers and the Board of Trustees during the past year, of the services rendered by your faithful and efficient secretary, Dr. John C. Forsyth, and Dr. George W. Wakeley, who will always find the place where there is work to be done.

May we all work together for the honor and prosperity of the New Jersey State Dental Society!

Dr. BURTON. You have heard the address of the president of the society. What is your pleasure?

Dr. WILKINS. Mr. President, I move that a committee of five men be appointed to act on the president's most excellent address. (The motion was carried.)

The following were appointed members of the Committee on the President's Address: Drs. Wilkins, Heckman, Stevens, Egel, and Rice.

Dr. Woolverton then resumed the chair.

The PRESIDENT. We will next have a report from the Committee on Necrology.

Dr. J. G. HALSEY, Swedesboro, then presented the

Report of the Committee on Necrology.

Your Committee on Necrology begs leave to submit the following:

During the year 1916 our Heavenly Father has called the following six members of the New Jersey State Dental Society to lay down their implements here on earth, and enter into that mysterious realm which is beyond our view, into which we must all at last enter, to give an account of our stewardship and to be rewarded according to our deeds, whether good or evil.

Dr. ELLISON ST. J. STACPOOLE, Fort Lee, N. J.; graduated from New York College of Dentistry in 1910; joined the State Society 1916; died February 1916.

Dr. EDWARD T. TAYLOR, South Orange, N. J.; graduated from New York College of Dentistry 1897; joined the State Society 1908; died January 2, 1917.

Dr. S. B. JOHNSON, SR., Dover, N. J.; began practice 1886; joined the State Society 1912.

Dr. JOHN S. BARRETT, Morristown, N. J.; graduated from New York College of Dentistry 1908; joined the State Society 1909; died January 1917.

Dr. FRANK W. FRENCH, Plainfield, N. J.; graduated from New York Dental School, 1899; joined the State Society 1912; died May 1917.

Dr. A. B. DEWEES, Camden, N. J.; graduated from Pennsylvania College of Dental Surgery 1895; joined the State Society 1908; died May 19, 1917.

As these names were being read some of us recall a relative, a friend or a neighbor, but to us all they were brothers. Therefore, as we pause for a brief space of time from our regular business to pay our last and heartfelt respect to these brothers, let us cherish their memories by remembering the many kind deeds they have done, the many noble acts they have accomplished.

Their work has been accomplished, their labors ended, and they are entitled to their rest. Let us remember them as friends we were delighted to meet, as companions who helped us to help others, and as co-laborers who have earned their reward.

JOSEPH G. HALSEY,

CHAUNCEY M. F. EGEL,

GEO. M. HOLDEN,

Committee.

RESOLUTIONS.

Whereas, by an act of Divine Providence, since our last meeting we have sustained the loss of our fellow member* ———— and

Whereas, it is the desire of our society to record appreciation of his association with us, and for his friendship; therefore be it

RESOLVED, That we, the members of the New Jersey State Dental Society, feeling deeply the loss we have sustained, hereby express our sorrow and our sympathy for the bereaved family; therefore be it

RESOLVED, That these resolutions be placed upon the minutes of this society, and that a copy be sent to the family.

Dr. JONES. I move that the report be received and spread upon the minutes.

Dr. FOWLER. I move an amendment to the effect that copies of the resolutions be engrossed and forwarded to the families of the deceased. (Carried.)

* These resolutions were repeated for each deceased member.

Dr. A. S. BURTON, of the Committee on Board of Censors, announced that the committee had no special report to make.

Dr. EDWIN R. MORRIS made the following report from the Committee on Oral Hygiene:

Report of the Committee on Oral Hygiene.

Mr. President and gentlemen of the State Dental Society of New Jersey.—Your Oral Hygiene Committee reports having held one meeting, at which time there were ten members present.

The duty intrusted to this committee as indicated by your favorable note on the matter of the compilation of a pamphlet or booklet, suitable for distribution to the laity, upon the subject of Oral Prophylaxis and Preventive Dentistry, has been accomplished.

Your committee begs to report the collection of sufficient data to formulate such a pamphlet, but feels that, inasmuch as the subject is such a broad and vital one, a special committee of five members should be appointed to edit the copy submitted by the Oral Hygiene Committee.

Dental clinics throughout the state report almost double the number of patients and operations over last year's report.

Your committee also reports having been instrumental in assisting in the preliminary work in many localities where dental clinics are about to be established.

The members of your committee have given many lectures in civic centers in their own localities upon the subjects of mouth hygiene and proper care of the teeth.

Your committee wishes to express the great need of live committees on Oral Hygiene in all of the component societies for the purpose of stimulating interest and enthusiasm in this important propaganda which will shortly be upon us.

The subject of the care of the mouth and its contents is now engaging the minds of those foremost in medicine, and presently there will be precipitated upon us a responsibility which we cannot in any way evade. Therefore your committee asks renewed individual enthusiastic support to the Oral Hygiene propaganda, to the end that Jersey may maintain a coveted position.

Such data as could properly be used in lectures, addresses, or discussions relative to the hygiene of the mouth is in the hands of your committee, and will be turned over to

its successors for your use on any occasion requiring it.

Your committee feels it to have been a distinct pleasure and privilege to have served the society, and we severally urge an earnest continuance of the work which was turned over to us by the former committee in such a splendid manner last year.

Respectfully submitted,

EDWIN R. MORRIS, *Chairman.*

Dr. WELSH. I move that the report from the Committee on Oral Hygiene be accepted and recorded in the minutes. (Motion carried.)

Dr. A. L. WESTCOTT, for the Committee on Entertainment, reported on the arrangements made to entertain the members of the New Jersey State Dental Society at Turner Hall on Friday evening at 8.30 with a smoker, to which the members and exhibitors in attendance at the convention were invited.

Dr. C. M. F. EGEL made the following report from the Legislative Committee:

Report of Legislative Committee.

During the last winter there were two bills introduced in the legislature that directly affected the profession of dentistry. One aimed to lower the standard of preliminary education. Your committee asked for a hearing on the bill, which was granted, and after presenting the arguments against this bill, it was killed in the committee that it was referred to—the Public Health Committee.

The other bill was a party measure and a blanket bill to cover all the professions in the state, making it mandatory upon them to name three men for each vacancy in their boards of examiners. This bill was passed. We would have preferred to have had the law remain as it was in regard to our profession, as this makes the appointment more of a political measure, but realize that our safety is in naming men eminently qualified for the position.

Respectfully submitted,

CHAUNCEY M. F. EGEL, *Chairman.*

Dr. HOPKINS moved that the report be accepted and spread upon the minutes. (Motion seconded and carried.)

Dr. JOHN C. FORSYTH, secretary, read the report of the Committee on State

Board of Registration and Examination in Dentistry.

Dr. HOPKINS, in view of the fact that these items had been published in the *New Jersey Dental Journal*, moved that the reading be dispensed with, and that the report be embodied in the minutes of the convention. (Motion carried.)

The next order of business was the report of the Exhibit Committee, by G. W. WAKELEY, chairman, as follows:

Report of Exhibit Committee.

Your committee wishes to report a most successful exhibit. We have sold nearly eight hundred running feet of space, and collections have been very satisfactory. As chairman of the committee, I wish to express my sincere thanks to those who have helped to make the exhibit the record-breaker that it is.

G. W. WAKELEY, *Chairman*.

Dr. J. G. HALSEY, chairman of the Committee on Ethics, reported as follows:

I believe I am the chairman of the Committee on Ethics. The most favorable report that the committee can make is that there is none to give. I have heard nothing to the contrary from any of the other members of the committee.

Dr. JONES. Mr. President, in appreciation of the important aid rendered to this society by the officers of the Society for the Suppression of Vice and Imposture, I move that the thanks of the New Jersey State Dental Society be extended to those officers for their valuable services. (Motion carried.)

On motion the convention adjourned until 8 P.M.

WEDNESDAY—Evening Session.

The president, Dr. Woolverton, called the convention to order at 8 P.M.

The PRESIDENT. We have with us tonight a gentlemen whom you all have heard, and many of you have read his works—Dr. KIRT H. THOMA of Boston,

Mass., who will read a paper on the subject of "The Histological Pathology of Alveolar Abscesses and Diseased Root-ends."

[This paper is printed in full at page 13 of the present issue of the DENTAL COSMOS.]

Dr. ALBRAY. Mr. President, I move a vote of thanks be extended to Dr. Thoma for his excellent paper. (Motion seconded and carried.)

The society then adjourned until Thursday, at 9 A.M.

THURSDAY—Morning Session.

The President called the convention to order at 10 o'clock.

The PRESIDENT. The next business in order is the nomination and election of officers to serve for the ensuing year. There are to be elected a president, vice-president, secretary, treasurer, and after these officers are elected we choose members by ballot to be recommended as members of the Board of Registration.

ELECTION OF OFFICERS.

The result of the election was as follows:

President—Dr. R. A. Albray, Newark.

Vice-president—Dr. George W. Wakeley, Orange.

Secretary—Dr. John C. Forsyth, Trenton.

Treasurer—Dr. J. G. Halsey, Swedesboro.

Nominations for Examining Board—Dr. John C. Forsyth, Trenton; Dr. F. L. Manning, Red Bank; Dr. S. I. Callahan, Woodstown; Dr. Franklin Rightmire, Paterson; Dr. R. B. VanGieson, Montclair; and Dr. G. H. Grim, Jersey City.

Delegates to the National Dental Association—Dr. C. M. F. Egel, and Dr. W. H. Gelston.

The list of nominations for the Board of Trustees of the State Society was as follows:

M. B. Shoemaker (Atlantic Co. Soc.); A. Zabriskie (Bergen Co. Soc.); E. C. Stillwell (Central Dental Association); R. A. Albray (Clinical Club); W. J.

Webster (Hudson Co. Soc.); Geo. W. Wilkins (Mercer Soc.); W. W. Hodges (Middlesex Co. Soc.); F. L. Manning (Monmouth Co. Soc.); J. B. Keller (Passaic Co. Soc.); C. M. F. Egel (Plainfield Soc.); W. H. Gelston (Southern N. J. Soc.); L. R. Fritz (Tri-County Soc.); S. M. Hinman (Union Co. Soc.).

Adjourned until 8 P.M.

THURSDAY—*Evening Session.*

The meeting was called to order at 8 P.M. by the president, Dr. Woolverton.

The PRESIDENT. We have with us Dr. WESTON A. PRICE of Cleveland, Ohio, president and managing director of the Research Institute of the National Dental Association, who will now address you on the subject of "Some Lessons Growing Out of Recent Studies of Oral Infections."

Dr. Price gave an extensive extemporaneous lecture on the work done by the Research Institute of the National Dental Association on the relation of oral infections to systemic diseases.* In closing this lecture Dr. Price made an appeal for support of the Research Institute, as follows:

Dr. PRICE. I want to thank you, gentlemen, and I would like to take just a minute to tell you how and where the work of the National Research Institute at Cleveland is carried on, and how it is being done. The work done in Cleveland is but one part—and a very small part—of the work that is done by the Institute. We have only a staff of four or five people, and we should have five times as many workers. The higher class of work has been supported in nine different cities by such workers as Dr. Hartzell in Minneapolis, who receives twenty-four hundred dollars, and Dr. Marshall, who receives three hundred dollars and is devoted to the study of saliva and dental caries; Dr. Frederick S. McKay of Colorado Springs, three hundred dollars; Dr. Noyes of Chicago, four hundred dollars;

Dr. Dunn of Ann Arbor and Dr. Prinz of Philadelphia receive five hundred dollars; and Dr. Howe of Boston and Dr. Callahan of Cincinnati—and all these men and all that work have been available simply through contributions of the dental profession. This work has been done outside by these men with contributions from three thousand men in the dental profession, and your splendid state, I think, had five subscribers of the three thousand. Without this support this work could not go on. We have, however, received from your state or from your organization the splendid contribution of last year of five hundred dollars to the National Association; one hundred dollars of that for the Research Institute for which we are a thousand times grateful to you. Work cannot be continued on the direct basis, and therefore it is being transferred to the universal one-dollar basis. Seventy-five per cent. of the dentists in the United States in the National Dental Association have made their arrangements to have the work continued on the one-dollar basis and have taken favorable action, and others cannot do so until an amendment is adopted at their next meeting, for their constitution in some cases will not let them do that without that action. Your society has not taken action. I trust your officers will give you an opportunity to do so. Do you want them to do so? Do not applaud unless you want the officers to do so.

Dr. ALBRAY. Mr. President, I move you that we extend a vote of thanks to the essayist for the splendid address to which we have listened this evening. (The motion was unanimously carried.)

Dr. PRICE. I thank you very much, but I would a great deal rather have you take a vote on the other proposition.

The PRESIDENT. All in favor of raising the dues one dollar for the benefit of the Research Institute remain standing.

(Most of the members in the hall remained standing.)

On motion, the meeting adjourned until Friday morning at 9 o'clock.

* [This is not published here for the reason that we have not received revised manuscript of the lecture.—ED.]

FRIDAY—*Morning Session.*

The President called the convention to order at 9.30 A.M., and introduced Dr. J. J. MOFFITT of Harrisburg, Pa., who addressed the members on "The Treatment and Filling of Root-canals for the Prevention and Cure of Alveolar Abscess."

[This paper is printed in full at page 1185 of the December issue of the DENTAL COSMOS.]

The PRESIDENT. You have heard the address of Dr. Moffitt; what is your pleasure?

Dr. HOPKINS. I move a vote of thanks to Dr. Moffitt for his splendid paper. (Motion carried.)

The PRESIDENT. In order to carry out the wishes of the convention, a motion to postpone for the present the report on the President's Address and go on with the business of considering the proposed new amendments to the Constitution is in order.

Dr. HODGES. Mr. Chairman, I move that we postpone for the present discussion and consideration of the recommendation of the Committee on the President's Address, and go on with the business of the adoption of the proposed new amendments to the constitution.

Dr. FOWLER. Mr. Chairman, I second the motion. (Motion carried.)

Dr. GELSTON then read the proposed amendments to the Constitution and By-laws, and moved their adoption. (Motion carried.)

Dr. GELSTON. Mr. President, I move the adoption of the Constitution and By-laws as a whole. (Motion carried.)

The PRESIDENT. The Secretary will read a letter from Dr. Logan, of the National Dental Association, on the Black Memorial.

The Secretary read the letter, as follows:

CHICAGO, Ill., June 20, 1917.

Dear Dr. Woolverton,—Just a brief note to convey my best wishes for a successful State Dental meeting and to ask as a favor on behalf of the Black Memorial Committee that you urge the New Jersey members of the National who intend to contribute to this fund to give

it their prompt attention. If your officers think it wise to consider a contribution of one or two hundred dollars from the State Society treasury, allow me to inform you it would be greatly appreciated.

Besides the individual contributions we have received from the Illinois State Dental Society one thousand dollars, one thousand from the Chicago Dental Society, two hundred from the Iowa State Society, two hundred from the Ohio State Society, two hundred from the Minnesota State Society, two hundred from the New York State Society, one hundred from the Missouri State Society, three hundred from the Indiana State Society, one hundred from the Second District Society of New York, and fifty dollars from the American Dental Club of Paris.

Fraternally yours,
W. H. G. LOGAN, *Chairman.*

The PRESIDENT. It would seem to me desirable that this society appropriate a certain amount of money for that purpose, and a motion to that effect would be in order. What is your pleasure?

Dr. FOWLER. Mr. President, the object for which this letter is written is a worthy one. It is of importance to the dental profession of this country, and we as a society feel that we must do our part in aiding this sort of thing—paying to honor the men who have blazed the trail. I therefore move that \$100 be appropriated for the purpose indicated in the letter which has just been read by the secretary.

Dr. BARRY. Mr. President, I second the motion. (Motion carried.)

The PRESIDENT. We will next hear the report from the Auditing Committee.

Dr. HILLMAN. Mr. President, the Auditing Committee has examined the reports of the Secretary and Treasurer, and finds them correct.

WM. TALBOT,
F. K. HEAZELTON,
G. H. HILLMAN,
Committee.

Ordered to be embodied in the record.

The PRESIDENT. We will have a report from the Preparedness Committee, by Dr. Stevens.

Dr. STEVENS then read the following report:

Report of Preparedness League Committee.

The New Jersey dentists were the first to register. The committee, through Dr. Forsyth, has about completed an inventory of the free dental clinics of the state.

Out of 1629 dentists in the state cards have been returned from 1197. These men have offered to place the mouths of 4941 recruits in fit condition, and to give 2191½ hours per week for any dentistry work the Government may require. Of the 1197, 344 have signified their willingness to serve in a base hospital or the dental corps, and 636 have signified their willingness to work for the conservation of the practice of a brother dentist who may be serving at the front.

An inventory of all the surplus dental instruments in the state has been made by this League.

J. B. STEVENS, *Chairman.*

Dr. STEVENS. I move that this committee or the chairman of this committee be requested to work in conjunction with the National Preparedness League, in so far as it possibly can. (Motion carried.)

Dr. GELSTON. Dr. Price has suggested that it would be well to send the check for the Research Institute of the National Dental Association at Cleveland to the treasurer of that institution, and that it be embodied in Art. XIV, Sec. 2, of the Constitution and By-laws. This clause has been embodied in that section, and has already been adopted.

Dr. BARRY. As you all know, the State Board of Registration and Examination this year is to be appointed practically under a new law; that is, the recommendation of three men by this convention to the Governor for each position, from which he accepts one, and makes the appointment. In order to clarify this matter, and in order to make it perfectly legal, since the adoption of the amendment to our Constitution and By-laws, I would like to make this motion, in order that we may be working along the proper line, and so that we will not get into legal difficulties with reference to this matter.

I therefore move that we ask the President of this association to recall and reconsider the announcement made by him to this convention deciding that certain men were elected for recommendation to

the Governor at yesterday's (July 12th) session.

Dr. ALBRAY. Mr. President, I second the motion. (Motion carried.)

The PRESIDENT. We will now have the report from the Treasurer.

Dr. JONES. Mr. President, I have two reports, one as the treasurer of the Indigent Members' Fund, and the other that of the New Jersey State Dental Society. I will now read the Fund report:

Report of the Treasurer of the Indigent Members' Fund.

TO THE PRESIDENT AND MEMBERS OF THE NEW JERSEY STATE DENTAL SOCIETY:

Ladies and gentlemen,—The treasurer of the Indigent Members' Fund begs leave to report as follows: That carrying out the wishes of the society at its last annual meeting held in Ashbury Park, ten shares of building and loan stock of the Rail and Harbor City Building and Loan Association of Elizabeth, N. J., of a par value of \$2400, was subscribed for in the name of the Indigent Members' Fund of the New Jersey State Dental Society, and I have to report that during the year a dividend of 6 per cent. was credited on the shares; that \$100 was appropriated to a widow; that a check for \$150 was forwarded to Dr. Wayne Babcock of Philadelphia for surgical services rendered, but that out of the goodness of his heart Dr. Babcock returned the check, for which I think the society owes him a vote of thanks.

The Board of Trustees invested \$500 of the fund in ten \$50 3½ per cent. gold bonds of the Liberty loan; therefore the state of the fund is as follows:

| <i>Receipts.</i> | |
|----------------------------------------------------------------------------------------|------------|
| Balance as per 1916 report | \$1,276.45 |
| Bank interest received during the year | 37.46 |
| Total | \$1,313.91 |
| <i>Disbursements.</i> | |
| Rail and Harbor City Building and Loan Association, 10 shares and initiation fee | \$121.00 |
| Widow | 100.00 |
| Liberty loan | 500.00 |
| Total | 721.00 |
| Balance | \$592.91 |

Respectfully submitted,

CHAS. F. JONES, *Treasurer.*

The PRESIDENT. You have heard the report by our Treasurer; what is your pleasure?

Dr. GELSTON. I move that we accept the report, with one exception—that in the report we strike out the name of the indigent member who is to receive the benefit from this fund, and that the report become a part of the records of this convention.

Dr. JONES. I accept the exception. (Motion carried.)

Dr. WILKINS. Mr. President, in the name of the New Jersey State Dental Society I have a most pleasant duty to perform. But a few years ago our machine was in danger of stopping, and at that time Dr. Jones became the pinwheel, and supplied the wherewithal with which to keep it from going backward. His services have been appreciated by this society, and in the name of our organization I want to present to him this token of our appreciation.

Dr. Wilkins, on behalf of the society, presented a handsome gold watch to Dr. Jones.

Dr. JONES. Mr. President, and fellow members, this is a great surprise to me. I did not anticipate anything of the kind, and certainly will prize this beautiful gift always. In thanking you I wish to add that I trust the work I have done has met with your approval, and feel that it must have been so, else you would not have made this handsome present to me. I thank you.

Dr. BARRY. In order to straighten out this matter with reference to six members recommended for the State Registration Board, I now move that the six men who received the highest number of votes and were selected at the meeting of yesterday, July 12th—Drs. Forsyth, Manning, Rightmire, Callaban, VanGieson, and Grim—be recommended to the Governor for the specified number of appointments, and that they now be declared elected by this convention.

Dr. GELSTON. Mr. President, I second the motion.

The motion was carried, and the president declared them elected.

The PRESIDENT. The next business in order is the report of the Committee on the President's Address. I will ask the president-elect, Dr. Raymonde A. Albray, to take the chair, and in the name of the New Jersey State Dental Society I now present him with the gavel. I wish to express to you, Dr. Albray, my good wishes, and hope that you may have the co-operation of the members and the Board of Trustees as I have had during the past year.

Dr. ALBRAY. Dr. Wilkins will report from the Committee on the President's Address.

Dr. WILKINS then read the following

Report of Committee on President's Address.

Mr. Chairman and gentlemen.—Your committee appointed to consider the President's Address submit the following report:

(1) The first recommendation contained in the address is "That the position of business manager be made permanent, with full control of the staging of the convention, empowered to make all contracts with the exhibitors, collect money on the same, with such other duties as may be directed by the Board of Trustees, and that he be compensated in a reasonable amount for such services."

(2) "That a complete record of the transactions at each meeting of the Board of Trustees be furnished to each component society, so that the society may devote more time to the educational side of the convention."

(3) "That the reports of the various committees, unless they contain matter to be discussed by the society, be read by title, and printed in full in the *New Jersey Dental Journal*."

(4) "That a committee of three be appointed to bring the history of the New Jersey State Dental Society up to date, from the time of reorganization."

(5) "That a director of membership be appointed to carry on a campaign with the slogan—'One thousand members at our 50th anniversary in 1920.'"

We, the Committee on the President's Address, concur in the above recommendation, move its adoption, and further recommend that the director's assistants comprise the chairman of the membership committee of each component society.

(6) "That a manager be appointed to take

charge of the portable motion-picture machine owned by the society."

We, the Committee on the President's Address, concur in the above recommendations, and move their adoption.

L. M. HECKMAN,
CHAUNCEY M. F. EGEL,
J. B. STEVENS,
CHAS. A. RICE,
GEO. W. WILKINS,

Chairman.

Dr. GELSTON moved that the clause in recommendation No. 1 be stricken out which states that the business manager shall make all contracts, but the chairman of the Exhibit Committee shall remain as previously and work in conjunction with the director or manager.

Dr. BARRY. I second that motion. (Motion carried.)

Dr. GELSTON. Mr. President, I move that the recommendations of the Committee on the President's Address to this convention be adopted as a whole.

Dr. BARRY. I second the motion. (Carried.)

Dr. FORSYTH. I have been requested to present the following resolution:

RESOLVED, That the New Jersey State Dental Society heartily indorses the bill adopted by the National Dental Association, July 27, 1916, which seeks to modify the status of the Dental Corps of the United States Army so as to increase the efficiency of the dental service to the Government, and bring to an end the existing discrimination against the profession of dentistry in the public service; and be it further

RESOLVED, That the amendment introduced by Mr. Lodge to the Bill (H. R. 4897) to amend Sec. 10 of the National Defense Act, approved June 3, 1916, and for other purposes, carrying out the purposes of the National Dental Association as heretofore recommended, be also indorsed; and be it further

RESOLVED, That the members of the New Jersey delegation in Congress be respectfully requested to lend their active support to the National Dental Association in its effort to accomplish this worthy object, and that the Legislative Committee and all other members of this association be instructed to use their best efforts to enlist the support of said members of the New Jersey delegation in Congress in behalf of this work; and be it further

RESOLVED, That a copy of these resolutions be transmitted to Senators J. S. Frelinghuysen and William Hughes, the congressmen of this state, and to Dr. Otto U. King, general secretary of the National Dental Association.

The PRESIDENT. You have heard the resolution; what is your pleasure?

Dr. EGEL. Mr. President, I move that this resolution be adopted. (Motion carried.)

Dr. CHAS. H. SPAHN, chairman, presented the report of the Clinic Committee, as follows:

Report of the Clinic Committee.

By Dr. CHAS. A. SPAHN, Newark, Chairman.

CONDUCTION ANESTHESIA. (By Dr. HERMANN PRINZ, Philadelphia; Dr. WALTER F. BARRY, East Orange.)

This clinic consisted of demonstrations of conduction anesthesia with the use of novocain. On both days the clinic was more than crowded, showing the interest in this particular branch of dentistry. In every case a minor surgical operation was performed, the patients being school children of Atlantic City. Those who attended this clinic were given the opportunity to perform the necessary operation upon the patients provided, all work being done under the direct supervision of the clinicians.

It is the intention of the Clinic Committee that demonstrations of this character be given so that men interested in a particular branch of dentistry should have the opportunity to perform some operation in that branch, under the direct supervision of capable instructors. It is thought that in this way the best results from clinics will be obtained.

AN ORIGINAL METHOD OF OUTLINING THE ARCH FOR ORTHODONTIC PROCEDURE. (By Dr. PERCY N. WILLIAMS, New York.)

Dr. Williams demonstrated an original method for outlining the arch for orthodontic procedure which seemed to create considerable interest. The demonstrations that he gave can be minutely

studied in July 1917 DENTAL COSMOS [see page 695]. This branch of orthodontia is now passing through an evolutionary stage, and it is suggested that those who are interested follow this branch of study in order to substantiate the work that our different investigators have given us to date.

MOUTH DIAGNOSIS. (By Dr. BERTRAM B. MACHAT, Brooklyn, N. Y.)

This clinic can truly be accepted by any dental organization throughout our country, being one of the newest and most accurate means of determining the internal conditions of a tooth and the surrounding parts based on scientific bacteriology, pathology, and physiology. It therefore has a direct bearing on the most vital topics discussed by all thinking medical men.

STEREOSCOPY, SINUS AND TOOTH RADIOGRAPHY. (By Dr. A. C. M. HERDLING.)

The ease and accuracy with which twenty-two plates were produced at the clinic prove conclusively the absolute necessity for the required equipment in every dental office, regardless of the branches in which the operators might be accustomed to labor, in order that intelligent diagnosis and treatment may be instituted.

THE RELATION OF SKIN MANIFESTATIONS TO ORAL FOCI. (By Dr. H. J. KAUFFER, New York.)

Dr. Kauffer showed a transparency three feet square containing the photographs of skin lesions, and radiographs of oral foci directly related to one another, with a statement of the importance of recognizing these conditions as they present themselves. This subject seems to be one that should be continued in our future clinics.

CORRECT IMPRESSION-TAKING. (By Dr. ROBERT H. LIEBERTHAL, New York.)

Fortunately, in this clinic we were able to secure a patient who had had ten full upper and lower sets of teeth made, the difficulty being entirely due to the lack of accuracy in securing the proper

impressions. Correct impressions taken scientifically by advanced methods based on Greene's principle were demonstrated by the clinician to be a pleasing, satisfactory, and almost a guaranteed method of producing a denture that the patient eventually can use.

Criticism by the audience during this clinic was most favorable.

On motion the report of the Clinic Committee was received.

The PRESIDENT. Dr. Slade desires to address the convention.

Dr. A. R. SLADE. Mr. President, we have among us a certain number of dentists who through their patriotic sentiment have enlisted. There has been considerable discussion as to what was the best way to preserve their practice, in attempting to prevent their incurring unnecessary loss if they are able happily to return to it again. Many suggested plans are not feasible. While the proposition that I now present to you is not enough for those who wish to do their full duty by the League, it is practical, and I believe will be acceded to by all practitioners. The proposition is simply this: As soon as a dentist in a community enlists, the dentists in the vicinity will begin to keep account as to who was the previous dentist of every man or woman entering their offices. Upon the return of the dentist—if happily he returns—he shows a list of the names of his former *clientèle*, and each dentist who has worked for those patients gives him a list of them. And let the Preparedness Committee of this society be instructed to prepare a letter for the man who has attended these patients to address each one of them somewhat after the following manner: That Dr. So-and-so is pleased to announce that Dr. So-and-so, after having been in the government service and having happily returned, has resumed his practice at such-and-such a number on such-and-such a street, etc. The dentist, returning later, simply prepares an announcement that he has resumed practice on such-and-such a street. There is no semblance here of delivering patients. In other words, we speak of a

practice as perhaps an individually owned property. I do know that a practice is something tangible, and that to return to that dentist all individuals of that practice who desire to return to him will set him on his feet quicker than if he had to start life all over again.

For that reason I move that the Preparedness Committee be instructed to prepare two letters as outlined, and that the dentists of the state be appealed to and obligated, in so far as they will reply, that as soon as an individual dentist in any community enlists, they will keep a record of each new patient, and upon his return present to that dentist a list of the names of his patients who attend his office, and will send to each of such patients a letter as indicated, implying that the practitioner returns the patient to the returned dentist.

The motion was carried.

FORMAL INSTALLATION OF OFFICERS.

President Albray having been called to the chair, upon the presentation of the

report of the Committee on the President's Address, when the president presented to him the gavel, now responded as follows:

President ALBRAY. *Mr. President and gentlemen of the convention*,—I appreciate the honor which has been conferred upon me, and I will endeavor to do everything possible to further the best interests of the New Jersey State Dental Society.

I wish to ask Dr. Wakeley, vice-president, to come to the platform, that I may introduce him.

Dr. Wakeley appeared on the platform, together with Dr. Forsyth, secretary-elect, and Dr. Halsey, treasurer-elect, and all were introduced by the president.

Dr. ALBRAY. Is there any further business? If not, a motion to adjourn *sine die* is in order.

On motion the convention adjourned *sine die*.

Eastern Association of Graduates of the Angle School of Orthodontia.

Eighth Annual Meeting, held in New York City, May 7 and 8, 1917.

(Continued from vol. lix, page 922.)

MONDAY—Morning Session.

(Continued.)

THE President announced as the next item on the program for the morning session the reading of a paper by Dr. MILO HELLMAN, New York City, entitled "The Relationship of the Sizes of the Teeth to the Form of the Dental Arch."

[This paper will appear in an early issue of the DENTAL COSMOS.—ED.]

The society then adjourned until the afternoon session.

MONDAY—Afternoon Session.

The meeting was called to order by Dr. Ferris at 3 o'clock.

Dr. J. A. CAMERON HOGGAN of Richmond, Va., presented a lecture on "Orthodontic Treatment of Advanced Cases and Patients Coming from a Distance."

[This paper is printed in full at page 45 of the present issue of the DENTAL COSMOS.]

DISCUSSION.

Dr. J. Lowe Young, New York. I have examined the casts and can see that

in cases of missing teeth—mutilated cases—results of considerable value might be obtained with this technique; but I hate to think of having to go to the trouble of making these metal dies for each tooth in the ordinary case of malocclusion.

Dr. Hoggan spoke about making an appliance for the case every two months from these casts, to be used by the dentist who was helping him to treat the case. I do not see why that should be necessary, unless the case was something very different from the ordinary.

Dr. G. W. Grieve, Toronto, Can. The idea many dentists have had for a long time is that they have only to wire the teeth to the appliance; it is not the appliance, but the man behind the appliance, that is the chief factor. I do not see how the work can be done by a dentist without any definite knowledge of orthodontia. It seems to me that the man who manipulates the appliances in the mouth of the patient should have a definite knowledge of the work, because he should be able to judge as to the effect of the action of the appliance.

Dr. J. V. Mershon, Philadelphia, Pa. I think Dr. Hoggan's whole thought in this matter was to present a technique which under many conditions and circumstances an orthodontist could make use of, and I think he has done it very well.

Dr. C. A. Hawley, Washington, D. C. There is no question that a case will be very much better treated if we can do it ourselves, and attend to all the technique; but I take it that is not Dr. Hoggan's proposition at all. There is going to be, and there is now, a great deal of orthodontia done by dentists in small towns. They think they have to do it, and it resolves itself into a proposition something like this: They will stumble along without any comprehensive idea of what they are doing, or else it will be done under the direction of some man who knows what should be done. I think a plan of this kind would enable a dentist to do the work better in certain situations. I do not think Dr. Hoggan has presented this as an ideal

method, or one in which you would get the highest and most artistic results; but it is far better than for a dentist in a small town, who does not know much about it, to attempt it alone. For that reason it is a very good method.

The idea of arranging the teeth cut from a model goes, in a way, back to the old scheme we have seen so many times, of dentists sawing off teeth in the laboratory, and arranging them, and trying to get an idea of where they should go. No matter how efficient all our methods are for measuring the teeth and determining the arch, it is not as comprehensible to the average dentist as this method of making a cast of the teeth, and then rearranging them. You see the thing clearly before you, and you get a better understanding of it.

The defect in the method of sawing the teeth from a plaster cast and rearranging them lies in the fact that the plaster is friable, and you do not have, finally, teeth of the exact dimensions of those in the mouth. If the teeth can be reproduced accurately in metal and rearranged it would be valuable in studying possible results and procedure in treatment as well as for the fitting of appliances.

Dr. H. E. Kelsey, Baltimore, Md. I might ask Dr. Hoggan if he really meant that every two or three months he constructed a new appliance, or does he readjust the old one? It would mean a great deal of work on the part of the operator who is seeing the patient, as well as on Dr. Hoggan's part, to have a new appliance inserted every two or three months.

The President. Dr. Hoggan's technique is ingenious, and undoubtedly would be of assistance in determining a normal occlusion, but he makes one statement that, in view of our present information, strikes me as peculiar—*i.e.* that in most all cases teeth take the same arch form.

Dr. Hoggan. I said when I set the same case up half a dozen times, they assumed the same form.

The President. Then I misunderstood you, Dr. Hoggan. If a man can-

not read a plan, and the appliance is not intelligible to him, I think this method may be of assistance; but, personally, I see no advantage over a plaster model, unless it be for the adjustment of appliances. One of our New York men, Dr. Wilbur Dailey, fifteen or eighteen years ago read a paper before the Second District Dental Society, I think, in which he said he carved out all the plaster teeth and set them up in wax.

In studying cases of malocclusion we can see the buccal cusps and buccal inclined planes very readily by these methods, but we cannot see the lingual inclined planes. We also lose the position of the axis of the tooth. With little practice, one can become proficient in reading a plan, and then his evidence is measurable and positive, and is intelligible to a third party. That is the reason for architects and engineers developing plans and projections for a proposed structure. By Dr. Hoggan's method you must lose space in making the teeth, and Dr. Stanton's oclusograph shows that a 2 mm. error in tooth material is sufficient to throw a set of teeth out of occlusion. I commend the chart and plan method, and hope it will be universally adopted.

Dr. Hoggan (closing the discussion). I appreciate Dr. Hawley's expression of my position, that I am simply endeavoring to get a possible improvement in a condition that is unfortunate. I claim that orthodontia is an art, and I can with my hands do things much more rapidly than I could with machines or mathematics, but I do not pretend to say that anyone else could not utilize another system to much greater advantage.

I admit there is a possibility of error in the casting of teeth. I know that when I cast these teeth from a wax pattern there is still greater chance of error. Dr. Young, when I showed this to him last January, drew my attention to this point, and I then placed my wax patterns back into the original impression—so there is not the same chance of error.

In regard to Dr. Ferris' suggestion, that perhaps a chance of error as great as two millimeters would lead to an obstacle that was greater than one which

would occur where a plan had been made on paper: Emphatically I would say that when I place these teeth back into the impression, those contact points are in contact and are touching. You can see they are in contact, and you cannot measure any closer than that actual contact. The possibility of error would be in the recasting of teeth. When they come out of the impression they are still in contact, but I do not believe they are perfect.

I do not believe this plan, or any other, will enable a dentist to bring teeth into an arch so that there is not two millimeters difference in normal occlusion. I do not believe he can carry out the plan so accurately as to bring it down to within two millimeters of being right, by any plan.

A point that I meant to bring out was the use of this model in fractures. I have had a good many fractures, and have found that with a model of this kind I can do all the construction as if it were in the mouth, make my fracture appliance, and cement it in. I find it of great value in fracture cases. It enables us to do any work we wish outside of the mouth.

ELECTION OF OFFICERS.

The society then held a business session at which various committees reported, and officers for the ensuing year were elected. The election resulted as follows:

President—Dr. F. T. Murlless, Jr., Hartford, Conn.

Vice-president—Dr. A. Leroy Johnson, Springfield, Mass.

Secretary—Dr. E. Santley Butler, New York City.

Treasurer—Dr. Martin Tracy, New York City.

Adjourned until the evening session.

MONDAY—Evening Session.

The evening was devoted to a banquet to the members and guests of the society. Following the banquet Dr. N. W. JANNEY, New York, gave a lecture entitled "An Experimental and Clinical

Study of the Isolated Thyroid Hormone."

[This paper will be published in a later issue of the DENTAL COSMOS.—Ed.]

The society then adjourned until Tuesday morning.

TUESDAY—*Morning Session.*

The meeting was called to order by President Ferris at 10 o'clock.

Dr. F. L. STANTON, New York City, read a paper entitled "Movement of Teeth Predetermined by Engineering Instruments: Appliances Designed in Accordance with Analytical Mechanics."

[This paper is printed in full at page 39 of the present issue of the DENTAL COSMOS.]

DISCUSSION.

Dr. J. Lowe Young, New York City. Dr. Stanton, in these cases that are sent to you from men out of town, or by the general practitioner—let us say he sends you a set of plaster casts—do you make the tooth measurements from those in the beginning?

Another question is, Have you seen cases that have been treated by men in this way that were not anything like as satisfactory as these you have shown, but turned out disastrously to the patient?

The point I have in mind is this: I am not a Christian scientist, and I do not believe very much in absent treatment, because my experience has led me to the conclusion that there are no two cases that respond to treatment exactly alike. No man can conscientiously say that the result shown here this morning on these casts is not marvelous for a man who has had no experience, but I would be fearful of such a man meeting a case that did not respond, as I fear the patient would come to grief by the teeth moving faster than the surrounding tissues could accommodate themselves.

Dr. Stanton. I feel that, when I entered orthodontia, even with all the training I could get, I did not serve every patient in the best manner in which he might have been served. The rea-

son I have entered into this consulting work is because this body of specialists cannot even scratch the surface of the amount of work that is necessary to be done. Besides, most of the people who need it cannot afford to pay for the work.

The general practitioner with those books of plans has produced results that would be considered good for a specialist. One man has fifty cases under treatment. I am doing this work honestly, and if I find it is hurting people, I will stop it instantly.

I was about to abandon my profession on account of the unsatisfactory results obtained. I went into this investigation to solve this problem. If after making these arches in my own office, they do not hold a great deal better than they have in the past, I am not only going to quit the practice of my profession, but I am going to leave this society.

In this consulting work we must have an accurate reproduction of the teeth. We require an exact model of the whole case, and also plaster casts taken in small sections. Our tooth measurements are checked in every way. You can rest assured that if any general practitioner sends a case to me, I will not make maps unless I feel the patient will be benefited. Nothing to discredit our profession will be permitted in this consulting work.

Dr. C. A. Hawley, Washington, D. C. In furtherance of Dr. Young's question: You take it from your experience that the difficulties we have experienced in moving teeth are perhaps caused by the fact that the teeth responded differently; the tissues seem to be different? Is that because our appliances have not acted harmoniously in both cases, and that the tissues in all cases would move the same if proper forces were applied?

Dr. Stanton. What I have given you is the predetermination of the occlusal arch. I shall not attempt to answer the biological question as to whether teeth put into occlusion will stay, or why the various failures occur. My endeavor is to give to the general practitioner a method of doing sound orthodontia under proper conditions. I also hope this method will be adopted by dental colleges. You

men will be the ones to judge. If you see bad results from this work in patients' mouths, you should report it to this society, or put it on record.

Dr. Young. Let us say the amounts of tooth material of the upper and lower dental arches are identical. Will that always produce the same results?—I am speaking of the mesial and distal measurements. Take half a dozen arches, we will say. I do not know how much tooth material is in an upper or a lower; but say the same tooth material is in each of the six lower and six upper arches—will that always bring the same form?

Dr. Milo Hellman, New York. According to Dr. Stanton's remarks the main object he seems mostly concerned with is the movement of teeth. Are we being led to understand the word "orthodontia" to mean just the movement of teeth, or have we outgrown this notion through the influence of the progress made in the evolution of our specialty? If our principal aim is to obtain definite results, then we can only judge the act involving the treatment of a case from the beginning to the end, according to the degree of success attained.

I argued similarly two years ago when Dr. Stanton first brought up this subject. I maintained then, as I do now, that the value of his work will be proportionate only to the success of the final results obtained. If Dr. Stanton claims that his methods of treatment are better than those the profession has practiced up to the present day, can he also show that his results are better? What I am concerned with chiefly is the result. If we cannot show any definite result, the energy expended in the movement of teeth is useless and wasteful. It does not interest me to know that a tooth has been moved one way or the other, correctly or incorrectly, if on the removal of the appliances with which it has been moved it still exhibits a tendency to return to its former position. The two cases Dr. Stanton showed might be criticized as still possessing too much "overbite," therefore as far from being complete successes.

I should like to know the percentage

and number of cases in which Dr. Stanton has obtained better results than have hitherto been reported, or such results as a good many orthodontists are ready to show at any time. What can he show as final results that will overbalance the past achievements of the profession as a whole?

I demand an answer to my questions because Dr. Stanton, in a series of articles recently published, has attacked the procedures of the entire orthodontic profession. As a member of that profession I consider his accusations undeserved and unjust. Many of us are working just as conscientiously and just as earnestly as Dr. Stanton, and although we are all willing to recognize and give him due credit for such of his achievements as merit it, it is in my estimation not becoming for a member of this society to make statements that may be interpreted as a reflection of discredit on his fellow members.

Dr. F. T. Murlless, Hartford, Conn. I have the keenest appreciation of Dr. Stanton's conception of this method, and the strongest feeling of admiration for the work which he has shown. I have a very clear conception of the amount of ground he has had to cover, and the amount of work that has had to be done to arrive at these conclusions.

Dr. Stanton. I did not bring forward the idea that orthodontists were aiming to establish occlusion. I thought that had been heralded all over the world. When an orthodontist takes a case of malocclusion, no matter how much he knows about paleontology and anthropology, he must select mechanical devices to move the teeth.

It seems unfair to speak of end results in discussing such a paper as I have presented.

We are a body of specialists who believe in normal occlusion of the teeth. We are all agreed that when teeth are in malocclusion they should be moved to occlusion by mechanical devices, until such time as our biological investigations will enable us to prevent malocclusion.

The contention of my paper is that it is possible to predetermine in any case

the relative movements of the teeth to change them from malocclusion to occlusion; also that with the aid of plans appliances may be designed to execute the desired movements. No amount of biological knowledge will offset a faulty diagnosis made by examining plaster models and selecting appliances that violate mechanical laws.

Is there not enough spirit of fair play to rise up against such a criticism of this work? You challenge me for evidence. I have brought evidence. Is it not good?

Dr. A. P. Rogers, Boston, Mass. We are in the profession of orthodontia to obtain the best results for our patients. When a firm or corporation starts in business of any kind, the object usually is to obtain the best results for their stockholders. One of their first efforts in these days is to secure the services of efficiency experts in order to obtain results in a quicker and better way, if possible, than their competitors.

If I were to try to designate the direction of our effort, I should say that it had been up to this day a combination of the artistic and empirical, without overmuch aid from the science of mechanics. We have not until recently called in the expert in mechanical engineering, and we must soon recognize that we are unable to obtain the best results in the quickest way unless we apply the leading principles of mechanical efficiency as taught us by these experts. Irrespective of biological growth, and much else that cannot be defined, we must seek and find the true relation which exists between pure mechanics and physico-mechanics. We know that there must be close relationship, and it is going to be interesting and profitable for us to seek and find it.

The very best thing our society can do is to begin thinking along efficiency lines, and to study and adopt everything which will help us to be more efficient orthodontists, to the end that we can give our patients more effectual treatment.

Dr. A. L. Johnson, Springfield, Mass. I wish to ask Dr. Stanton if his arch form depends entirely upon the form and size of the first permanent molars.

Dr. Stanton. The arch form depends

on the size and form of every tooth in the arch. You cannot separate them.

Dr. Johnson. You start with the first molars?

Dr. Stanton. You must start somewhere.

Dr. Johnson. How did you answer Dr. Young a few minutes ago?

Dr. Young. My question was, If the mesial diameter of the thirty-two teeth was identical in half a dozen cases, would the arch form be identical? Dr. Stanton replied, No, because it would depend on the measurements of the tooth in every direction and dimension—not only the mesio-distal diameter, but the buccolingual diameter, and every other.

Dr. Stanton. If you would permit me, I should like to read before the society a paper on the vertical curvature and the treatment of the overbite. I have asked this society, as a test, to select three skulls with normal occlusion and widely varying arch forms, to see how nearly the oclusograph can predetermine occlusion.

Dr. Young. That is the proposition you made once before, about the determination of the arch from the skulls. You said that you must make the measurements of the teeth.

Dr. Stanton. You may sit by us, as we measure the teeth; no human being can say what form that instrument will take. You will see us drop in link after link, and when that crooked thing is straightened out, we will show the occlusal arch. We must take the teeth and measure them, and fit the molars together.

Dr. Young. Supposing we handed you these teeth in sections.

Dr. Stanton. You can hand us the teeth one by one, and take them back as they are measured.

Dr. H. E. Kelsey, Baltimore, Md. You mean that we are to bring the thirty-two teeth from a skull, and you will predetermine the arch?

Dr. Stanton. A dentist said he would like to see this test made. He handed us thirty-two teeth, saying it was one of the most beautiful sets of teeth he had ever seen. We put it on the oclusograph,

and no arch could be predetermined unless you extracted one of the teeth. There was a discrepancy in the tooth material. We tried the arches with various overbites, changing the arch form, but no arch could be formed without the removal of one of the teeth. We therefore formed an arch with three lower incisors and those teeth are being set up by an expert in anatomical articulation. He will set the molar teeth first, and when he gets around to the incisor region those three incisors will exactly fill the gap. We gave him the exact arch width, and he will have exactly the amount of space to put in three lower incisors. A report of that case will be published shortly.

Dr. Murlless. Do I understand that these teeth have been considered in perfect occlusion by the man who brought them to you?

Dr. Stanton. No, we gathered that; he did not say so.

The President. Why there should be any rancor or question about Dr. Stanton's sincerity I do not know, and I think that should be eliminated. I would entertain a motion that a committee be appointed to look into this matter. It only seems fair that any one of us who develops a thing worthy of consideration should have fair treatment.

Dr. Murlless. This matter in regard to the skulls is one in which we must all have misunderstood Dr. Stanton. Such being the case, I think the question really rests with him. He has reached the point where we can see what he is working for, notwithstanding the reluctance of some of us to accept this method *in toto*, and without evidence that exists only in his mind. Whether Dr. Stanton would like us to give him a final indorsement or not is largely his pleasure.

Dr. Stanton. I do not want any final indorsement, but I would like a test.

Dr. Hawley. I cannot see any need for an official test. If he is going to help us, let us receive it, and make all we can of it; but I cannot see that an official indorsement of a committee of three individuals will amount to much.

Dr. Young. As I saw the slides on

the screen this morning, every arch that Dr. Stanton showed seemed to me to be what I would say excessively wide in the cuspid region. I am not prepared to say it is not right, because I do not know; but if I treated my patients in that way, and gave them that kind of dental arches, I think I would have a great deal of dissatisfaction.

The second point is what he said about the determination of the overbite. I have come to the conclusion that the determination of the proper amount of overbite in the incisal region is the most difficult problem in all orthodontia, and I am firmly convinced that orthodontic treatment should be completed by the time the bicuspid and cuspid are in position; I cannot see how it can be determined before, unless some sort of radiograph is used. If Dr. Stanton can show us the amount of normal overbite in the incisal region, then I say he is a wizard.

Dr. Kelsey. I accepted Dr. Stanton's proposal and sent him a pair of models. I am endeavoring with appliances to produce exactly the arch forms indicated by the survey chart sent me. In the few months it has been under way, it has progressed very satisfactorily, but I have not yet reached the completion of the case. I only mention this because I think the time has come when anyone can test it out for himself, and perhaps that is one of the best ways of getting at the true value of the procedure.

The President. I have heard Dr. Stanton say that he would survey for charitable institutions. I do not know whether he would consider this organization as a charitable institution, but if he would open his doors to us, and extend an invitation to the men to have an individual trial, I think probably it would go far to satisfy the minds of the men as to the efficiency of his plan of procedure.

Dr. Stanton. I should be very glad to do that, although I can hardly say I consider this institution a charitable one!

A vote of thanks was tendered to Dr. Stanton for his presentation.

The President next introduced Dr. FLOYD S. MUCKEY, New York City, who gave a lecture and demonstration on "Phonation."

The next item on the program was the reading of a paper by Prof. WILLIAM

KING GREGORY, New York City, on "The Evolution of the Human Face."

[This paper will be published in an early issue of the DENTAL COSMOS.—Ed.]

The society then adjourned.

(To be continued.)

Dental Society of the State of New York.

Forty-ninth Annual Convention, held at Rochester, N. Y., May 10 to 12, 1917.

(Continued from vol. lix, page 1258.)

FRIDAY—*Evening Session.*

An informal banquet was held at the Powers Hotel, on Friday evening, at 7 o'clock. There was a large attendance, and a most enjoyable entertainment was provided. Dr. H. J. Burkhart acted as toastmaster.

Dr. BURKHART. I wish to express, on behalf of the committee in charge, their very great pleasure and gratification in seeing so many present tonight. It is a most unusual thing for a State Society banquet to have over two hundred in attendance, and this marks a new era in State Society affairs.

I hope the dinner will be one of the functions at each annual meeting, in order to give the members an opportunity to get together, not for the purpose of listening to ten or fifteen toasts, but to listen to the two or three speakers specially selected for the occasion, and for another purpose which will be most pleasing to you. I want to personally congratulate the Local Committee on the splendid work they have been doing at this meeting, and I think you all have your hats off to the chairman of the Exhibit Committee, Dr. Link.

I take very great pleasure in presenting to you a gentleman who really does not need to be presented, because he has the right to present himself—our friend

from Buffalo, the president of the New York State Dental Society, Dr. Murray.

PRESENTATION OF FELLOWSHIP MEDAL.

Dr. MURRAY, on behalf of the society, in presenting the Fellowship Medal to Dr. James R. Callahan, Cincinnati, Ohio, spoke as follows:

Dr. MURRAY. *Dr. Callahan*,—One of the important and delightful functions of our State Society meetings, made possible by one of our most highly esteemed and beloved members, Dr. Jarvie, is the ceremony of electing Fellows of the Dental Society of the State of New York.

Section 26 of the By-laws provides that—

The Committee on Nomination of Fellows shall, at each annual meeting, recommend to the Council the name of a dentist who, in their judgment, has contributed results of original research, or of one whose high attainments and high standing have been of such character as to have materially aided and advanced the science and art of dentistry.

Those recommended must be natives or residents of the United States or Canada. They shall be elected Fellows of the Dental Society of the State of New York in the same manner as is provided for the election of honorary members, and shall be awarded a gold medal of design and inscription approved by the society, which shall be paid for from the interest

of the Wm. Jarvie Fellowship Gold Medal Fund.

By the authority vested in it by the by-law just read, this society has been signally honored in the past by being permitted in this impressive and tangible manner to honor some of the greatest scientists, some of the noblest and most lovable characters, in the dental profession on this continent.

To be permitted to have one's name enrolled as a Fellow of this society may not mean much to a man whose soul is aflame with devotion to his profession and whose time is fully occupied with the arduous and exacting duties of professional life; but to be permitted to have one's name added to the roster that bears the names of Black, Brophy, Darby, Jarvie, Miller, Talbot, Cryer, Jenkins, Andrews, Perry, Truman, Carr, Johnson, and Jackson is a distinguished honor devoutly to be desired, and an ample reward for a lifetime spent in the service of dentistry and humanity.

In selecting you, Dr. Callahan, as the 1917 candidate to receive this special mark of our esteem and love, the Committee on Nomination of Fellows had in mind your valuable services to dental science, and the self-sacrificing manner in which you have labored toward the solution of some of the most perplexing problems of our profession.

Your efforts toward the standardization of root-canal technique have placed your name high up on the roll of honor among scientific investigators, and have won for you well-merited praise and recognition by organized dentistry throughout the world.

Of your past life, history informs us that you received a high-school education in Hillsboro, Ohio, a country town of 3000 inhabitants, near Cincinnati.

Being the son of an old-fashioned family physician with office and residence combined, you had ample opportunity to develop latent talent, which pastime took the form of rolling blue-mass pills, putting up quinin powders, reading medicine, and assisting in the surgical work that came to the office. It was here also,

you received your first instructions in sterilization, where hands and instruments were usually sterilized in the same basin or bucket or whatever was most convenient.

After being graduated from the Philadelphia Dental College in the class of 1876-77, and working in an office in San Francisco for about three years, you located in your home town, and in 1889 moved to Cincinnati, where during the early years of practice you took special courses in the medical college. On account of your deep interest in matters pertaining to your profession you were called upon and served your state and local societies in official capacities for more than twenty-five years. Your first important contribution to dental literature that commanded attention was a paper read before the Ohio State Dental Society in December 1893, entitled "Sulfuric Acid for the Opening of Root-canals." This paper, with slight modifications, was read before the New Jersey State Society in 1894.

About this time your researches on tin and gold in definite proportions for filling a certain class of cavities attracted attention.

Your more recent contributions to dental literature were papers entitled "Rosin as an Adjuvant in Root-canal Filling," read in New York City in 1914, "Root-canal Preparations," read in Brooklyn and Boston in 1915, and "Branching of Pulp-canals and Multiple Foramina," read before the National Dental Association at a later date.

These valuable additions to dental literature were the cause of your selection to fill more honorable and arduous positions relative to the prosecution of scientific investigations in the field of dentistry, hence your appointment to membership on the medical staff of the Cincinnati General Hospital as director of the dental clinic; and, as a mark of esteem and confidence of the National Dental Association, you were made a director of dental research on "Root-canal Problems" under the auspices of the National Dental Research Institute.

The character of a man is often

judged by the company he keeps, and there is no better company than good books, and in this connection it is not surprising to learn that you have in your possession one of the most complete privately owned dental libraries in the United States.

It is said that every man has a hobby. This has the effect of not only maintaining a well-balanced mental equilibrium, but in your case furnished a profitable diversion from the exacting duties of professional life. We are credibly informed that your particular hobby is chicken-raising, in the prosecution of which you have accumulated some interesting data on this subject.

The best means of determining a man's worth is the esteem in which he is held by those with whom he associates, and it is not surprising to learn that Dr. J. R. Callahan is a great favorite not only in his home city but throughout the entire continent.

This society congratulates you on the honor and distinction that has come to you in your efforts to serve humanity, and I esteem it a peculiar privilege and pleasure on behalf of organized dentistry in this state to present to you the Wm. Jarvie Gold Medal, and proclaim you a Fellow of the Dental Society of the State of New York, and we as a society greatly appreciate the opportunity this occasion affords of expressing to you in this manner our love and esteem for the great service you have rendered the profession of dentistry and to suffering humanity.

Dr. CALLAHAN, in accepting the medal, said:

It affords me a great deal of pleasure to announce to you that I have been informed that I am expected to make about a three-minute speech, because of the very full program for the evening. Not only should the speech be brief, but possibly it should be of the character that was indicated by a letter I received a short time ago from a Northwestern society, inviting me to come to their state meeting to read a paper, and saying they would pay my railroad fare and hotel

bill. It was signed by the chairman of the executive committee, and it had as a postscript the following: "We would expect the paper to be worth the money it costs us." I replied on that occasion that I did not think I had anything that was worth the money, and I did not go.

On this occasion perhaps I should have said I had nothing that was worth the expense, but still I came.

The endowment of the Jarvie Fellowship I suppose was for the purpose of encouraging study on the part of the dentists, in order that we might better understand some of the problems that confront us. In my early life, when I first began to study dentistry, I received my first encouragement from a member of this society. It was before the old Mississippi Valley Association that I read a paper—my first paper. Jonathan Taft was present, and William H. Atkinson, and perhaps my friend Dr. Hoff, who is with us tonight. I think Dr. Hoff was just about able to walk alone at that time. Being my first attempt, and being quite a young boy, when I sat down I was in a perspiration, and I wished the floor would open up and swallow me. Dr. Atkinson came and sat near me, and put his hand on my shoulder, and said, "My dear boy, you are doing very well. Go on and study and work. Make the effort, and some day you will be able to write a good paper." [Laughter.]

Now Dr. Atkinson's society, the New York State Dental Society, has called me up and has said, "You are doing very well; keep it up."

If I do not appear to place proper estimate or value upon what has occurred in the last few moments, it is simply because I have not the words that are adequate to express my feelings, but I assure you I appreciate it very deeply. I feel that a greater honor has been conferred upon me than I ever dared to hope for. I thank you from the bottom of my heart, and I promise you I will endeavor to keep up the work as best I can.

Dr. BURKHART. I have the great pleasure of breaking a little news to you,

and of introducing the president of this society for the coming year, in the person of the president-elect of the Dental Society of the State of New York—Dr. Amos C. Rich of Saratoga Springs.

Dr. RICH. *Mr. Chairman, brother members, and friends,*—I appreciate this high honor more than I can say. My feelings are beyond what I could express to you. I hope I may be able to fill this office to the expectations of the members of this society, but to do that, I ask each and every one of you, and those who are not present tonight, to help me; and in turn I promise you to do the best that is within me. I thank you very much.

Dr. BURKHART. We would like to have a word from an old friend who has honored us with his presence tonight. He has been a guest of the Dental Society of the State of New York for many years.

I take great pleasure in asking my good friend Dr. Gaylord to address you.

Dr. E. S. GAYLORD, New Haven, Conn. *Mr. Toastmaster and gentlemen,*—It is quite a surprise to me to be called upon; but if ever I felt I would like to be able to make a speech, it is just at this moment. To be asked to be present at such a gathering as this is indeed a privilege that is well worth living for. To be able to attend for many years, as I have, your state meetings is always a privilege; to me it seems a duty, and I have often said I cannot afford to stay away.

It is a great satisfaction to be able to say even a word before such an audience as this. I knew before I came here that a good program would be presented. It is to be greatly regretted that that program has been interrupted, but the method of its interruption we all indorse for the sake of our dearly beloved country.

Now to digress a bit. I am known as the famous beggar of the National Association Relief Fund. I represent that committee, and I shall say just a word relative to that, because it is one of the things nearest to my heart. I want to live long enough to see \$50,000 in the

treasury, and then we will begin to aid the poor fellows who are suffering. Nearly half that sum is already in bank. The great work of the last year on your part has stimulated your committee to make efforts beyond former years, and if we all keep up in the manner we are doing—I hope this great calamity which has come over us will not interfere with it—one year more will complete that sum of \$50,000.

I also want to extend to you our thanks in aiding us so nobly in purchasing the Christmas seals.

The society then adjourned.

————— SATURDAY—Morning Session.

The meeting was called to order by the president, Dr. Murray, at 11 A.M.

The PRESIDENT. We have about arrived at the end of our program, and it may with truth be said that we are about to consider one of the most important—if not the most important item on our program—the paper by one of our own members, Dr. JOHN R. CALLAHAN of Cincinnati, Ohio, who will speak to us on the subject of "Logical Asepsis in Dental Practice."

[This paper is printed in full at page 31 of the present issue of the DENTAL COSMOS.]

DISCUSSION.

Dr. A. R. COOKE, Syracuse. It is undoubtedly true that our dental offices, as offices, are poorly arranged for the purpose. We have too many hangings, too many oriental rugs, too many domestic rugs, too many dust-catchers, too many dirty corners, too much rubbish lying around, and we are not careful enough in other ways. The only way of correcting my own errors would be to throw all the equipment I have in the scrap-heap, rent a new office, and begin at the foundation, for I want an office that can be cleaned. I want an office which I am not dependent upon the janitor of the block to come in and clean for me.

We have gone at the question of sterilization in a very haphazard way. We

have been buying a lot of nice expensive white-enamel furniture, and putting that up to catch the eye, to please the public, and lead them to think that we are being aseptic in our operations. Now, we are not aseptic in any sense of the word. I know I am not, and cannot be until I have a different office. There are many things we cannot do in our offices which the essayist has shown us ought to be done.

The matter of the sterilization of every instrument used for a patient before it is used for another case is absolutely essential, and can be practiced by anyone. Better care of the hands and of the materials we use is necessary. The essayist has shown that the ordinary paper points, while they may be sterile when made, are not sterile when we get them. We may sterilize our instruments in the sterilizer, and believe that they are sterile when they are taken from the apparatus. We bring them into the operating-room, put them in a case, the dust settles on them, and we no longer have sterile instruments. We may or we may not have pathogenic germs; we probably have many inoffensive ones.

I had hoped the essayist would tell us how to efficiently and properly sterilize such instruments as handpieces, which cannot be taken apart, in which the mechanism necessitates having a quantity of oil, and which we would like to have as clean as anything else.

In the matter of the care of the hands, I shall have to go home and get Dakin's solution, new brushes, new soap, and spend a great deal more time in scraping off these prehensile attachments of mine. I shall endeavor to find out what particular class of bacteria I carry around on my right thumb and index finger. We know what Dr. Callahan's brand is—he has told us.

While it is not possible for us to do all we ought, we certainly can do better than we have in the past, and if we are to get the results desired and are going to be safe and sane in regard to our patients, we must pay more attention to these things. I venture to say there are hundreds of offices in the State of New

York which have absolutely no means of sterilizing instruments, not even an old rusty pan, and yet we wonder why we have so much dirty dentistry. It is no wonder to me that we have periapical disturbances and many systemic effects.

I do not know how many infections my patients have carried home, but, fortunately for me, they cannot prove that they got them in my office.

Let us go home and reorganize; throw out the old rubbish and get some new sterilizers. Let us be more careful about our instruments, and be honest about it. If we do that, the law will hold us blameless.

I wish to thank Dr. Callahan for coming here and giving us this talk. I think it is particularly profitable at this time.

Dr. Charles F. Ash, New York. I feel sufficiently interested in this subject to want to take up a minute or two of your time, because of some points Dr. Callahan brought out, and because of some points Dr. Cooke brought out in the discussion. I think Dr. Cooke struck the keynote of the whole situation when he said, Be honest; that means, be honest with yourself and your patients. He struck another very good note when he said the thing to do is to go home and discard the old equipment and get a new one, and if necessary get a new office. I suppose not every dentist has enough ready money to discard everything and get all new equipment, but if it is possible to discard such of it as is not adequate, and put in some that is adequate, you will find that the money has been spent to good advantage. The lovely white enamel furniture has been catching the patient's eye, and possibly we have told the patients we had it because we did not want to cause infection—that it was sterile. We have been impressing upon people the fact that it is possible for them to get infections from such sources, and now the patients are going to catch the dentist. They are waking up to the possibility of infection in our offices, and will demand that sterilization and the antiseptic methods necessary to

protect them shall be followed out, and it will not be simply that the furniture be painted white.

A word about hand-brushes. If you have not used it, I would recommend a solution of potassium bichromate for keeping the hand-brush antiseptic. After you have used the brush, it should be washed out, put in the sterilizer and boiled, and when it is taken out of the sterilizer it should be placed in a glass container filled with potassium bichromate. After the container is thoroughly cleaned and filled with boiled water taken from the sterilizer, then put in just enough bichromate to give the water a deep orange color. It is not necessary to measure the exact percentage, because a little more than is necessary does no harm. I prefer that to lysol. It is a good antiseptic, and is not harsh on the hands. It is a good deal cheaper, too, costing about ten cents for four ounces. It is very comfortable to use on the hands, and does not leave any disagreeable odor. Brushes kept in this solution will remain sterile until you are ready to use them. With regard to handpieces, we put our handpieces right in the autoclave and sterilize them.

As to flowing steam, the objection I have to that is that it takes longer to sterilize anything with flowing steam than it does when put in the autoclave and sterilized under pressure.

Dr. Cooke. Will your handpiece stand the heat of the autoclave?

Dr. Ash. Yes. We usually wipe off the handpiece with alcohol, wrap it in gauze and put it in the autoclave. We use for waste receivers the paper containers made by Johnson & Johnson. Paper points, gutta-percha points, cotton, small napkins to be used for various purposes, and all such things, are put in the autoclave and sterilized. All instruments are put into boiling water and sterilized.

When I am ready to do root-canal work, I announce the fact to my nurse, and proceed to sterilize my hands. The cover from the jar that contains the brushes is removed, we start the water running, and use the brushes with a mix-

ture of green soap—we use the kind that is used in the hospitals; my nurse makes it gallons at a time, and we find it efficient and not expensive.

While I am scrubbing my hands with the brushes from the jar, green soap, and hot water, the nurse produces a package done up in an antiseptic towel, and lays it on the operating table. That towel is wrapped in an outside container, which is discarded when the aseptic towel is ready to be used. The instruments are taken from the sterilizer directly with a pair of aseptic forceps and placed on the towel.

The nurse has another package which contains the napkin that I dry my hands on, and also we have rubber gloves ready in case we want to use them throughout the operation. The rubber dam has already been applied, and we have gone through the usual sterilizing procedure that you are all familiar with.

Many times I have seen a man spoil his whole operation by going into a root and then putting that instrument with other instruments that are sterile. If you use an instrument in a root-canal once, and put it with other instruments, you spoil those instruments. I put everything into a tray, and everything that goes into that tray is sterile until it is used.

I know it is hard to get out of the old ruts, but it is our duty to our patients to do so.

Dr. F. W. Low, Buffalo. I understand, Dr. Callahan, that we have to be particular when we are doing root-canal work. Would you consider it necessary to take all those steps in view of the mishaps that occur in the dentist's office—I mean an ordinarily clean man—in doing work other than the treatment of root-canals?

Dr. Callahan. If I understand your question, I believe we should follow these aseptic precautions in everything we do. I will cite a case: A patient was sent into our ward in the hospital with an infected mouth, which had been infected in extracting a third molar. The patient was in a very serious condition. A suit was threatened. If it could be

shown that that dentist was not in the habit of following these lines of asepsis, that would settle the case.

Dr. Low. One of your slides showed the presence of different varieties of organisms. If the bacteria were dead, so they would not make a culture, what then?

Dr. Callahan. The smear from which the picture was made was taken from a culture. We did not obtain a pure culture from this case on account of an error in the technical work. The case was then thrown into the discard.

Dr. Low. Did you ever get a culture on taking out a root-filling that you considered perfect, to see if there were any possibility of infection there, after it was made by the most perfect filling method you knew of?

Dr. Callahan. No; that would be a valuable test in several ways.

Dr. Low. If we do not do that, we have not proved anything, in my estimation.

Dr. Callahan. The question of sterilizing the handpiece was mentioned. The method Dr. Ash spoke of is of course very effective. If you add a little bit of green soap to the water, and boil that, you can sterilize the handpiece. In some cities they have endeavored to pass a law that the barber shops should be examined and given certificates to the effect that they are using aseptic methods in their work; and in two places I know of the dentists were included.

Dr. Ash brought out the point that every instrument that has been used on an infected area should not be used again; it should be dropped into a glass dish. If the instrument were lying on the table I should be sure to take it up again, but it is the duty of the nurse to get it out of the way after I have used it.

Dr. Louis Meisburger, Buffalo. Would you consider it safe to have on your operating stand an evaporating dish with water in it at 90° C., in which to put the instruments? If you put them in this for three minutes, would you consider it safe to use them again?

Dr. Callahan. I would rather do it the other way.

Dr. Meisburger. You must give us something practical. I am afraid you are getting a little too pessimistic, and if I had not listened to Dr. Ottolengui yesterday, I would lose all hope. We must do something to improve our technique, but we must give the average man something he can use, and not simply to listen to at dental meetings.

Dr. Callahan. I do not think I have advocated anything that is impossible. It is your habits that you are afraid of.

Dr. Low. Besides the root-canal, you said we should take the same precautions with other work. If my hands and instruments are absolutely sterile, and I have gone into a bicuspid to excavate the dentin, if I take out one chip of the dentin must I put that instrument into the sterilizer again, or would I contaminate the cavity?

Dr. Callahan. You might get a different infection, because there are different kinds of micro-organisms at various depths.

Dr. Low. It simply shows that the question is one of absolute impossibility.

Dr. Callahan. My idea is to create the habit of thorough asepsis as nearly as I can. A lot of the work which you take for granted, because I have gone into the detail here, does not mean that I have advocated any extreme. I have advised you to buy the cheapest sterilizer that is made, and I have advised you to do the things that are protective to your patient. It is astonishing how they notice those things. Nearly every man, woman, or child of the educated classes understands what asepsis is. I want to cultivate the habit. I have had to correct myself very often, and still do so. If I lay an instrument down, I am sure to take it up again, and I have to be watched. My nurse watches me very carefully.

Dr. F. A. Ballachy, Buffalo. When you have laid down a broach which comes out infected, will close proximity contaminate other instruments, or must they be in contact with the infected broach? You stated, I think, that the whole surrounding area could be contaminated. Will it be by the air, or by contact?

Dr. Callahan. It would be difficult to answer that question definitely. We have two glass dishes in the cabinet, one for things discarded, and one for the things to be sterilized. The nurse removes these dishes after each patient.

Dr. Ballachy. Could the instrument stay in the dish until the end of the operation without contaminating your other instruments three or four feet away?

Dr. Callahan. I think so. On the bottom of each dish is a little water to which a few drops of formalin has been added. Be as clean as you know how, and keep it up. —

THE PRESIDENT. We now come to a very important matter, the purchase of a dental ambulance to be presented to the Government of the United States by the dentists of this state. It is a contribution in support of your government, and I want all who desire to contribute, who have not already done so, to give their names to the men who will pass up the aisles.

The report of the secretary of the Executive Council was then read. On motion, the report was received and adopted.

The next order of business was the installation of the newly-elected presi-

dent, Drs. Messerschmitt and Meisburger escorting the president-elect to the rostrum.

Dr. MURRAY. Dr. Rich, it gives me great pleasure to welcome you to the chair, and I hope the coming year will be one of as intense interest and profit to you as the past year has been to me. In taking up the official duties, I did so with considerable misgivings. I did not have very much experience in wielding the gavel in such important organizations, but as the work of organization proceeded, and the interest among the various members became manifest, I began to feel at ease, and the very able manner in which the members of the profession throughout the state have risen to the occasion has indeed been a gratifying experience to me. I sincerely hope and trust that the support that was so freely accorded me will be accorded to my worthy successor.

I now hand you the gavel of authority, and wish you every success in the coming year.

Dr. RICH. Gentlemen, I am not a speechmaker. I shall attempt to do my duty as a presiding officer, but beyond that, I shall be very quiet.

The society then adjourned until the next annual meeting.

THE DENTAL COSMOS

A MONTHLY RECORD OF DENTAL SCIENCE.

Devoted to the Interests of the Profession.

EDWARD C. KIRK, D.D.S., Sc.D., LL.D., *Editor.*

L. PIERCE ANTHONY, D.D.S., *Associate Editor.*

PHILADELPHIA, JANUARY 1918.

EDITORIAL DEPARTMENT

A Professional Appeal.

SOMEWHAT over a year ago we asked our wide circle of readers to give sympathetic consideration to an appeal for funds made by "l'Aide Confraternelle," a benevolent organization of our professional *confrères* of France the objects of which have a valid claim to our sympathy and support. We regret to say that the appeal brought but a meager response. We again direct attention to this charity, in the hope that a clearer understanding of the matter may bring out a more worthy practical expression of the spirit of fraternal helpfulness which dentistry has always shown in any time of stress or calamity affecting the *personnel* of its professional body.

Throughout Belgium and the whole area of French territory devastated by the war, practitioners of dentistry, in common with the rest of the population, have had in most instances their every

earthly possession swept away. Homeless, dependent families of dentists whose male heads have been mobilized or killed, dentists in civil life dispossessed of means of livelihood and now in dire need, are among those for whom the appeal for help is made by l'Aide Confraternelle, which is undertaking the investigation of all appeals of a dental professional origin and is wisely and economically distributing the collected funds in relation thereto. Nor is its larger objective concerned wholly with the alleviation of suffering among dentists and their families during the active war period. By its charter from the French government the organization is to be continued for a period of five years after the conclusion of peace, in order—

- (1) To facilitate the return to normal life of all colleagues severely injured by the war, by giving to them or advancing as an honorable debt the necessary means to re-establish themselves; and
- (2) In the invaded districts to help in the reconstruction of destroyed homes and in newly equipping dental offices devastated by the enemy, so as to enable dentists to resume their practice.

The officers and management of the organization are representative of the leading dentists of France, with a committee of patrons comprising the most distinguished leaders of the dental profession in that country, who together are chartered as an organization in conformity with the French law. The *personnel* of l'Aide Confraternelle in itself is ample guarantee of the strength of that body, and of the wisdom, philanthropic spirit, and economy with which its benefactions will be dispensed. Founded in March 1915, the association has collected up to the present time *Fr.*64,-968.05, *i.e.* slightly more than \$12,500, contributed almost wholly by French dentists; or, measured by the length of time during which the association has been in active operation, there has been collected less than \$5000 per year, which, considered in relation to the magnitude and importance of the objective, for which funds are desperately needed, is meager and wholly inadequate.

The dental profession of America is asked to contribute to a fund to aid destitute and distressed colleagues and their families in the war zone of our allies. Two aspects of this matter present themselves for consideration. The first consideration is a personal and intimate one, obviously because the cry for help comes from our brothers in distress. In every local case when the ap-

peal has been made to the dental profession of America the response has been liberal and prompt; that is to say, when we have understood and realized that the need was one within the limits of our own professional household. But we submit that the present one is precisely such a case. The war is now our war; we share its consequences in common with our allies; our professional household has thus been enlarged by the condition of war so as to embrace every colleague of the Entente nations in the membership of our immediate professional family. We repeat that "These colleagues who have lost all are dependent for relief upon the only enduring and saving human sentiment which stands out as a worthy human characteristic in this maelstrom of world-madness—the spirit of brotherly love." We believe that spirit to be keenly alive among all who struggle for the common blessings of equal freedom and justice to all—blessings which none may rightly enjoy without paying for them in terms of whatever available possession he may have, in service or in substance. We appreciate the fact that appeals for aid necessitated by war conditions are multitudinous, and that each is a pressing one; nevertheless, the meeting of these demands is a condition that war imposes, and none may escape the responsibility of doing his share even though that share shall be the final sacrifice—to help attain the goal. In the present case, in which the appeal is not for a general but for a particular need, a request for aid from dentists to their brother dentists, the opportunity thus afforded becomes a duty as well as a privilege. Prompt action, a little self-denial, and a moment's consideration of the immeasurable good that will result from a whole-hearted response by the dental profession of America to this appeal on behalf of our suffering French and Belgian colleagues and those dear to them, should put the required funds at the disposal of l'Aide Confraternelle without delay.

We ask each reader of this appeal to regard it as personally addressed to him. We ask the editors of all dental periodicals to re-voice this appeal in their several publications and to act as receiving stations for contributions, which may be sent direct to the Treasurer of l'Aide Confraternelle, M. FONTANEL, 1 Rue Vercingétorix, Paris, France. The DENTAL COSMOS will acknowledge and will so forward any contributions to the fund sent to its publication office addressed to the Editor.

BIBLIOGRAPHICAL

THE PRACTITIONER'S MEDICAL DICTIONARY. Containing All the Words and Phrases generally used in Medicine and the Allied Sciences, with Their proper Pronunciation, Derivation, and Definition. By **GEORGE M. GOULD**, A.M., M.D., Author of "An Illustrated Dictionary of Medicine, Biology, and Allied Sciences," "The Student's Medical Dictionary," "Pocket Medical Dictionary," etc. Third Edition, revised and enlarged. By **R. J. E. SCOTT**, M.A., B.C.L., M.C., Fellow of the New York Academy of Medicine, Editor of Hughes' "Practice of Medicine," Gould and Pyle's "Cyclopedia of Medicine and Surgery," etc. Based on recent medical literature. With many Tables. Philadelphia: P. Blakiston's Son & Co. Cloth, \$2.75.

While this book is not intended primarily for dentists, it contains much valuable information in a terse and comprehensible form that every dentist should have readily accessible. The definitions of some of the strictly dental terms are not all that could be desired, but are, we believe, on a par with the average medical lexicographer's conception of dental terms.

The eponymic terms have been placed in their proper alphabetical order rather than under the test, process, or disease with which the name is associated, and the compiler has inserted therewith the nationality and the dates of birth and death of those referred to, incidentally

affording the reader a very interesting and valuable historical record.

It is noticeable that the author has not entirely accepted the generally adopted method of dropping the final "e" in spelling certain medical and chemical terms, such as cocain, morphin, oxid, chlorid, and the like.

We recommend this book as a ready reference work for the dentist where he only desires briefly stated general information with regard to various diseases, medicines, terms, etc., with which he may be more or less unfamiliar.

ORAL ROENTGENOLOGY. A Roentgen Study of the Anatomy and Pathology of the Oral Cavity. By **KURT H. THOMA**, D.M.D., Lecturer on Oral Histology and Pathology and Member of Research Department, Harvard University Dental School; Instructor in Dental Anatomy, Harvard University Medical School; Captain Massachusetts State Guard Hospital Unit; Oral Surgeon Robert Bent Brigham Hospital; Visiting Oral Surgeon, Long Island Hospital; Member of National, State, and Local Dental Societies, and Interstate Association of Anesthetists; Fellow in the American Academy of Dental Science; Associate Fellow of the American Medical Association. With 311 illustrations. Boston, Mass.: Ritter & Co., 1917.

This book, as the title indicates, deals specifically with the use of the Roentgen ray as applied to dental practice, and

while the author is, as might be supposed, enthusiastic in his advocacy of roentgenology as an invaluable diagnostic means in dental practice, he does not overlook the fact that its greatest benefit is as an aid in confirming diagnoses of dental conditions made in other ways.

The author has wisely, we believe, accepted the nomenclature adopted by the American Roentgen Ray Society, along with the terms *radiolucent*, *radioparent*, *radiopaque*, and *radiopacity* suggested by Dr. R. Ottolengui, which latter we also believe to be etymologically sound and clearly explicit in their meanings.

There are, however, other terms used by the author, such as "temporary teeth," "wisdom teeth," and "supernumerous teeth," which we believe should be and have largely been eliminated from dental nomenclature.

The author particularly emphasizes the importance to the dental roentgenologist of an intimate knowledge of the internal anatomy of the bony structures of the head and face in order to be able intelligently to interpret roentgenograms, and has incorporated in his book quite a little of the anatomy of the structures under consideration. In this connection he has given a very clear description, supplemented by diagrammatic charts, of the relations of the developing teeth to the other structures during the transitional period from the deciduous to the permanent denture.

The book abounds in well-printed illustrations which aid materially in elucidating the text. The illustrations are reproductions of roentgenographic negatives which show the conditions as the roentgenologist is accustomed to view them in the X-ray film. Illustrations made from positive photographic prints, as is usually the case in illustrating

roentgenographic pictures, are frequently misleading unless the observer is trained in their interpretation.

We feel that every dentist who is equipped for roentgenographic work will derive much benefit from the perusal of the pages of this book, and particularly from a close study of the numerous illustrations contained therein.

A MANUAL OF DENTAL PROSTHETICS.

By GEORGE HENRY WILSON, D.D.S.,
Professor of Prosthesis and Metallurgy in the Dental Department of Western Reserve University, Cleveland, Ohio; Special Professor of Prosthesis in the Dental Department of the University of Southern California, Los Angeles, Cal. Third Edition, revised. Illustrated with 439 engravings. Price, \$4.50. Philadelphia and New York: Lea & Febiger, 1917.

The third edition of this deservedly popular book on Prosthesis has been fully revised, and will undoubtedly be welcomed by all dentists who practice this branch of dentistry. Dr. Wilson's well-earned position as an authority on matters pertaining to prosthetic dentistry assures an attentive audience to whatever he writes in his special field.

The author has included in the third edition further investigations of the physical properties of plaster of Paris and vulcanite, and it is interesting to note in this connection that he is still firm in his conviction that plaster of Paris is the best material for taking impressions of the mouth for prosthetic work, notwithstanding the increasing number of adherents to the use of modeling compound for this purpose. In summing up his conclusions with regard to impression materials he states very positively his preference for plaster when he

says, "The more difficult the case the more essential is the plaster-of-Paris impression."

The author pays tribute to the work of Greene and Supplee in awakening the profession to the possibilities of impression-taking and stimulating renewed interest in prosthesis.

Description of the Hall method of antagonization, along with a description of the Hall Antagonizer, is given in a clear and concise manner, the author summing

up his opinion of this method and instrument by saying, "They are remarkably simple, positive, and efficient," and unhesitatingly indorses the method as one which he believes "destined to revolutionize the mounting of artificial dentures."

Dr. Wilson's book has been brought up to date as a whole, and no student or practitioner who is interested in prosthetic dentistry can afford to be without this latest addition to the literature of the subject.

REVIEW OF CURRENT DENTAL LITERATURE

[*Lyon Médical*, August 1917.]

Mercurial Stomatitis: Its Pathogenesis, Prophylaxis, and Treatment. BY M. FAVRE.

Favre is convinced that the stomatitis which develops under mercurial treatment is identical in every respect with Vincent's ulceromembranous stomatitis. The mercury merely induces local congestion and irritates the vessels, thereby encouraging the extensive multiplication of Vincent's spirochaetes. Any drugs which kill these organisms cure the mercurial stomatitis even when mercury is continued. Arsenic and silver nitrate are the most effectual. The arsenic can be given internally or intravenously or by local application. This method of giving neosalvarsan with the mercury allows the full therapeutic effect of the mercury, while warding off trouble in the mouth. For local treatment silver nitrate is more effectual than arsenic.

The treatment which Favre has found promptly successful in hundreds of cases begins with the mechanical cleansing of the mucosa of the patches and membranes. This is done with cotton-wound toothpicks dipped in 1 per cent. silver nitrate. The ulcerating mucosa is rubbed vigorously and cleansed of

all purulent masses and pseudomembranes, working between the teeth, and thus transforming the inflamed mucosa into a red, freely bleeding surface. The mucosa thus prepared is swabbed with a 1:15 or 1:20 solution of silver nitrate, working it into all crevices, and the procedure concludes with the copious application of 1 per cent. methylene blue. The first treatment is always the longest and the hardest to bear. On the following day the appearance of the lesions is much modified, and the functional symptoms have improved. The swabbing is continued once a day, and later at longer intervals. It is soon possible to have the tartar removed from the teeth, and to put the mouth in a good condition. With hygiene of the mouth, gargling with hydrogen dioxid, and brushing the teeth, there is no return of the buccal infection, even though the mercurial treatment is continued unmodified.

Herpes Zoster, a Focal Infection. BY EVERETT S. LAIN.

After a study of focal infections from a dermatological standpoint for nearly three years, observing several hundred cases, and

after consultation with and corroboration by other men, the author is quite convinced that focal infection from the mouth and tonsils plays no small part in a certain class of skin diseases. After conscientiously prosecuting this work in quite a number of cases of zoster, and after observing in many cases rapid recovery or improvement after removal of the offending tooth or other foci, Lain is fully convinced that there is a true herpes zoster which has its origin in a specific infection, having a focal point most frequently in pus pockets surrounding or at the apices of one or more teeth.

Although Lain assures the reader that he is conservative and critical in his observations, the brief case histories which accompany this article do not in themselves suffice to prove the contention. They are not even illustrative. If the cases referred to really afford convincing evidence, their histories have been introduced in too abbreviated a form.

[*Journal of the American Medical Association*, October 20, 1917.]

Alcresta Ipecac. REPORT OF THE COUNCIL ON PHARMACY AND CHEMISTRY, A. M. A.

This is a brief note contained in the well-known column "Propaganda for Reform." In 1915 Alcresta ipecac tablets (Eli Lilly & Co.) were admitted to "new and non-official remedies." Since that time advertising claims, less modest than the earlier ones, drew the attention of the Council to this preparation. Among this advertising material were statements to the effect that ipecac alkaloids have a demonstrated usefulness in pyorrhea. "Such an unequivocal statement is unwarranted. In spite of the enthusiastic advocacy, in the past, of ipecac alkaloids as a specific in pyorrhea alveolaris, the preponderance of scientific evidence indicates that ipecac is of questionable value in this condition."

On the basis of this and other extravagant claims it will be necessary to omit Alcresta ipecac from "new and non-official remedies."

[*Den Norske Tandlaegeforenings Tidende*, July 1917.]

St. Apollonia and Her Picture in the Nidaros Breviary. BY JOHN WESSLER.

The earliest picture, so far discovered, of St. Apollonia is reproduced as a frontispiece

to Wessler's article. It was discovered by him in London in 1914. This, the oldest known painting of the patron saint of dentistry, is artistically delineated on a sheet of parchment in an old breviary, dating from the end of 1300 A.D. The breviary belonged to a Dominican cloister in Flanders. The picture is framed by the V in Virgo at the beginning of the text, which is in Latin in Gothic script. A translation here follows:

Concerning St. Apollonia, Virgin and Martyr. For us, O Apollonia, pray heartily to the Lord, lest for our sins we be afflicted with sickness in our teeth.

Versiculus. Pray for us, blessed Apollonia, that we be made worthy. *Let us pray.*

Oratio. Eternally omnipotent God, for whose honor blessed Apollonia, virgin and martyr, steadfastly suffered the horrible crushing-out of her teeth, grant Thou as we desire, that we may be made happy in commemoration of her, through whose most pious intercession we were freed from toothache and all imminent evils. Through Christ our Lord. *Amen.*

Another breviary, that of Nidaros, in Norway, printed in 1519, of which three copies are extant, has recently re-awakened interest, in that its title-page—which was missing in all three existing copies—has been found in Griefswald, Germany. In Wessler's opinion there is no doubt that also here we have to do with a representation of St. Apollonia, although the picture which comprises the title-page of the breviary is not accompanied by other evidence than the forceps.

[*Lancet*, London, October 6, 1917.]

A Case of Vincent's Infection Involving Mouth, Eyes, and Penis. BY F. B. BOWMAN.

After a gradual onset of about two weeks' duration, the local lesions and the systemic condition were so bad that the patient had to be admitted to a hospital. There was a severe conjunctivitis, with copious thin discharge and photophobia. The mouth was half open, and the lips covered with angry herpetic-looking ulcers. The gums were reddened, the teeth bathed in pus, pressure on the gums caused severe bleeding. Three days later there was found on the penis a small red ulcer with a membrane over it surrounding the meatus. Smears made from all three areas showed

large numbers of Vincent's spirochaetes and fusiform bacilli.

Treatment with the following prescription as a mouthwash, with admonition not to swallow, quickly cleared up the condition:

| | |
|-------------------|--------|
| Vini ipecacuanha, | 3ss, |
| Glycerini, | 5j, |
| Liq. arsenicalis, | ad 3j. |

Clinical Methods of Treating Hypersensitive Dentin. BY HERMANN PRINZ.

A necessary prerequisite to any rational method of treating hypersensitive dentin is a consideration of the factors, structures, or conditions which permit of this hypersensitivity.

The entire question of a nerve supply to the dentin is still *sub judice*. Prinz suggests that if there are nerve fibers in the dentin, they are not of a sensory or motor type, but are trophic in function.

However this question may be decided in the future, for the present Prinz advances a simple adequate explanation of the mechanism of hypersensitivity. The basis of this theory is the practical incompressibility of water. The sequence of events as Prinz pictures them is somewhat as follows:

There is a break in the enamel covering. The thereby exposed fibrillæ of the dentin absorb water from the saliva and swell; then the slightest pressure upon this swollen dentin will be transmitted through the odontoblastic processes to the bodies of the odontoblasts, and these in turn will compress the nerve plexus underlying and encircling the odontoblasts.

The validity of this explanation is supported by the clinical experience that dehydration will remedy hypersensitivity. The warm-air blast, alcohol, and acetone will dehydrate dentin, but penetrate so short a distance that frequent repetition is necessary. Sharp instruments used with dexterity conduce to minimize the pressure exerted upon the swollen dentin.

The use of agents which anesthetize the tooth by lowering its temperature is unsatisfactory.

Two classes of drugs may be used to overcome the hypersensitivity—caustics and anesthetics. Among the caustics are mercuric chlorid, silver nitrate, zinc chlorid, sodium

or potassium hydroxid, and phenol. All these agents act only superficially, and their application must be continually repeated. Consequently, except in slight cases of hypersensitivity, they are rather unsatisfactory.

The condition of analgesia induced by a general anesthetic, *e.g.* nitrous oxid, is not completely satisfactory. So deep an anesthesia that all sensation is inhibited alone meets the requirements of many cases.

Prinz's views upon local anesthesia and the technique of its induction are so well known and so accessible that they need not be given here.

In closing, he emphasizes the danger and needlessness of resorting to copyrighted preparations used for desensitizing purposes. The employment of preparations containing arsenic or formaldehyd is pleasantly satirized.

[*Den Norske Tandlaegeforenings Tidende*, June, July, and September 1917.]

Aneurysms of the Arteries of the Head and Neck. BY HOLBAEK-HANSEN.

This article is written in German, and hence is accessible to a much larger circle of readers than if it had been presented in one of the Scandinavian languages.

To follow this work intelligently through-out it will first of all be necessary to be informed of the author's definitions and classification. A pathological condition of the arterial wall is the essential character of an aneurysm. The pathological process must have affected and altered the intima, media, and adventitia—either one of these layers or all together. Five forms are distinguished, viz:

I. Aneurysma verum diffusum—an extensive widening of the arterial wall. According to the form and structure these genuine aneurysms may be subdivided as (a) Aneurysma fusiforme et A. cylindroides; (b) A. circosoideum.

II. A. verum circumscriptum s. sacciforme.

III. A. mixtum. In this form one or two of the arterial walls are expanded after separation of the arterial layers from each other. (a) A. mixtum sacciforme; (b) A. dissecans—here the adventitia in a somewhat marked degree is, after a circumscribed perforation of the inner layers, raised up off of them.

IV. Aneurysma spurium s. traumaticum—also known as an arterial hematoma. The

blood escapes, after a wounding of the arterial wall, into the surrounding connective tissue, and here is collected either as (a) A. spurium traumaticum diffusum, or as (b) A. spurium circumscriptum—here the escaped blood is collected into a sac.

V. A. arterio-venosum.

These are the forms to which the author makes recurrent reference. If an aneurysm be manually and instrumentally accessible it is known as an external aneurysm; if in whole or part manually and instrumentally inaccessible it is called an internal aneurysm. Clinically only the two chief forms, A. verum and A. spurium, are of interest. The latter form in most cases is encountered in the external aneurysms, while the true aneurysms practically are met with in all arteries. Clinically, a pulsating tumor, communicating with an artery and filled with arterial blood, fulfils the general concept of an aneurysm. The false aneurysms are encountered more frequently than the true forms; of the latter the *circumscriptum* and *mixtum* predominate. Age, sex, and occupation play a definite rôle in the occurrence of aneurysms. Most of the aneurysms occur between the ages of thirty and forty, and forty and fifty. Their number in males exceeds that in females. However, aneurysms of the arteries of the head and neck, extra- as well as intracranial, occur approximately in both sexes with equal frequency. These lesions are found generally in the working classes, particularly in men with hard and long bodily labor.

Although the genuine extracranial aneurysms play a very small rôle in comparison with that of the intracranial forms, still for the dentist the latter type is relatively of less interest.

Microscopically the media is found to have undergone the greatest change in cases of aneurysmal alterations of the vessel wall. The at present dominant view is that a mes-arteritis and an endarteritis are the most important factors in the etiology of the true aneurysms. Holbaek-Hanssen mentions syphilis, arterio-sclerosis, and joint rheumatism as among the causes of this inflammatory change in the vessel wall. Apropos of the etiology of the aneurysms of the arteries of the head and neck, it may be said that the anatomical relations and the intra-arterial blood pressure work together with (1) syphilis for the

intracranial forms in general, although here arterio-sclerosis may be a factor; (2) arterio-sclerosis for the extracranial forms, particularly for the carotis communis and its branches in the arteries of medium size, e.g. carotis interna. The author was unable to find in the literature a case where an aneurysm of the carotis communis was associated with syphilis.

In this connection may also be mentioned (a) aneurysms which are conditioned by mere increase of the intra-arterial blood pressure, the anatomical relations, and the physiological functionings; (b) the embolic-mycotic erosion aneurysms—which are very rare in the region of the head and neck, although the literature records an aneurysm of the internal carotid following a dental abscess.

There are two classes of symptoms from intracranial aneurysms—(1) those which arise from a direct action of the aneurysm on the brain substance, and (2) those which are seen when the several cranial nerves are exposed to the pressure of the aneurysm. Among these symptoms the trigeminal nerve may be affected, with consequent severe pains in the orbit and attacks of facial neuralgia. (Cf. Shannon, 1917: Case of an aneurysm of internal carotid, intracranial portion, and its effect on patient's vision, *Arch. of Ophthalmology*, New Rochelle, Nov., p. 518.) Facial paralyses have been observed, especially after ruptures of the aneurysm. At times a facial edema rapidly follows the development of an aneurysm of the common carotid.

Obviously the diagnosis of external aneurysms is essentially easier than in the case of the internal forms. An aneurysm at the middle third of the internal carotid, and also one of the external carotid, by displacement of the posterior belly of the digastric may condition a swelling immediately behind the angle of the mandible. A certain sign of aneurysm of the internal carotid is said to be a systolic rustling in the region of the parotid.

Aneurysms of the external maxillary artery are great rarities. On the external arteries of the head and neck aneurysms are often formed; but they naturally are rarities and are in most cases purely traumatic injuries of the vessel walls, with consequent formation of an aneurysm or arterial hematoma. Among the head and neck arteries, which border on the oral and pharyngeal cavities, aneurysmal

formations in the internal maxillary artery have been found. The diagnosis is not easy. Generally these are of traumatic origin.

In respect to extracranial aneurysms the symptomatology is more distinct and capable of differentiation than in intracranial aneurysms. In particular, aneurysms which are in the region of the oral cavity or pharynx are readily confused with tonsillar and retropharyngeal abscesses. In all cases an exact examination and a thorough history of the condition have great influence in securing correct interpretation. When it is desirable to decide whether an aneurysm is localized on the internal or external carotid, the temporal artery on each side is observed. If there be no difference in the rhythm of the pulse it is probable that an aneurysm of the external carotid can be excluded.

Aneurysms which have been conditioned by gunshot wounds are relatively rare on the cervical arteries. When the frequency of the wounds of the head and neck seen in the present war are considered, it must be admitted that the aneurysms in question are relatively rare. In part this is to be explained by the fact that wounds seriously involving these arteries bring death before help can come. In part the elasticity of these arteries and their possibility of being shoved aside by the missile account for the infrequency of traumatic aneurysms. Likewise aneurysms which have been caused by stabbing and cutting instruments are rare, because the wounds leading to the outside from these arteries are so large that there is no opportunity for thrombosis and sac formation. It is also peculiarly noteworthy that aneurysms after wounds to the bones of the head and face are not often seen. Aneurysms in the head and neck regions are relatively frequently seen after operative procedures. Fischer mentions an aneurysm of the internal maxillary artery which Surraige observed after the extraction of a third molar.

A summary of the purely traumatic extracranial aneurysms found in the literature, including two within the author's own experience, is as follows: Internal carotid, 6; internal maxillary, 4; external maxillary—superficial temporal, deep temporal, and ascending pharyngeal, each 1.

The author carried on some animal experiments (rabbits) to determine the forms of the

wounds, resulting in aneurysms, which could be inflicted by sharp, cutting objects. In only two instances was he successful in producing aneurysms artificially. These experiments are detailed and their significance discussed.

The treatment of aneurysms is divided into two groups—(1) general, and (2) local. The former method is usually the only one applicable in the case of internal aneurysms. The essential feature of this is to keep the patient in a condition of absolute rest, so as to equalize and minimize cardiac activity. In the case of intracranial aneurysms iodine preparations show a favorable action. When it is known that the lesion is of syphilitic origin many authors recommend iodine, mercury, and salvarsan. Operative interference can also be resorted to, in the form of ligature of the internal carotid.

The operative or local treatment plays the greater rôle in the case of the aneurysms of the head and neck arteries. The methods here applicable are those of Hueter and Hunter. Hueter's method consists in the ligation of the afferent and efferent arteries as closely as may be to the sac and when possible the total extirpation of the aneurysm. In the case of small aneurysms of the external and internal carotids (the latter very rarely), thyroid, lingual, and any of the superficial arteries whose anatomical relation warrants the employment of this method, Hueter's technique is followed.

For Hunter's method a point on the afferent arterial branch is chosen, and here it is ligated. In the case of the larger cervical arteries, and the extracranial arteries covered by muscles and fat, and in the case of all intracranial arteries, Hunter's operation is that indicated.

So far as the author knows, arterial suture or transplantation has not yet been applied to cervical arteries for eradication of aneurysms.

In looking back over this very extensive report on cervical and cephalic aneurysms one must admire the diligence and care with which Holbaek-Hanssen has presented so thoroughly such an unusual topic. Although it has but slight affinities with the exigencies of general dental practice, though relatively and absolutely rare, it becomes of interest at this time, when the frequency of such lesions is increased in the casualties of warfare.

Facial Paralysis Following Pasteur Antirabic Treatment. BY ROBERT L. LEVY.

There are records of only 150 cases in which paralyzes have followed the use of this treatment, and of these patients but 25 died. Levy reports here a case of facial diplegia with onset 73 days—an exceptionally long latent period—after the beginning of the prophylactic inoculations. This is an unusual form of "treatment paralysis." The author includes in this article a table and analysis of 10 other cases of facial paralysis, from the literature, following antirabic treatment.

[*British Medical Journal*, November 17,
1917.]

The Relative Germicidal Efficiency of Antiseptics of the Chlorin Group and Acriflavin and Other Dyes. BY H. D. DAKIN AND E. K. DUNHAM.

"The object of the following paper is to point out certain common errors in the testing of antiseptics of the chlorin group which lead to totally inaccurate inferences as to

their germicidal potency; secondly, to compare the results obtained by methods eliminating these errors with those furnished by other antiseptics; thirdly, to examine the claims for the alleged vastly superior germicidal potency of acriflavin and certain other dyes; and lastly, to indicate how important the matter of the velocity of disinfection is in forming a judgment of the utility of antiseptics in surgical practice, and also the methods suitable for their successful employment."

After a detailed report of the extensive experiments *in vitro*, the authors summarize their work as follows: "(a) The rapid and complete disinfection brought about by solutions (one volume) of members of the chlorin group of antiseptics of the strength commonly used in the treatment of wounds, when added to heavily infected blood serum-muscle extract mixture (two volumes); (b) under similar circumstances, solutions of acriflavin, proflavin, brilliant green, and malachite green failed to sterilize in six hours mixtures which the chlorin antiseptics sterilized completely in five minutes or less."

PERISCOPE

Using Beeswax.—When beeswax is left immersed in water that is too hot, its useful working qualities are impaired. A blanching or whitening of the surface shows that it has been heated to too high a temperature. A rather large volume of water at the right temperature (about 40° to 50° C.) should be employed, and full time allowed for the beeswax to become warmed and softened throughout.—D. M. SHAW, *Dental Record*.

Dental Neuralgia or Pain Referred to Branches of the Fifth Nerve.—Patients who have only the roots of carious teeth remaining may suffer much from neuralgic headaches, referred to various parts of the head, but often appear to have lost the toothache which they had prior to the crowns of the teeth breaking off. They are then reluctant to believe that the roots left are the cause of the headache, for, as they express it, they

"have no toothache now, only headache." I often tell them that the result of the referred pain is much the same as the confusion which exists in a servant's mind as to which bell has been rung in a house.

It is not infrequent for patients to seek medical advice for what they believe to be inflammation in the ear, while on examination the ear is found to be quite free from trouble, although a posterior molar is badly affected. An opposite case is where patients insist on having a number of sound teeth extracted, while the real trouble is the far more serious condition of disease of the Gasserian ganglion. Occasionally pain, usually caused by a diseased lower molar, is referred to the shoulder or arm, and is then apt to be wrongly diagnosed as neuritis. Reflex paresis or paralysis affecting the arm has occasionally disappeared on extraction of an offending tooth.—T. WILSON SMITH, *British Dental Journal*.

Taking Impressions with Modeling Composition.—When the compound is molded properly on the tray, immerse the external aspect of the tray for a few moments in cold water—this prevents the heated metal causing discomfort and sometimes pain to the lips—dry and dust the surface of the compound with a fine quality French chalk, and take the impression. This method gives very fine definition, the compound does not stick to the teeth, and the general result is a source of pleasure to the dentist and his patient.—*Oral Health.*

Inlay Strengtheners.—When you are having trouble in making an m. i. d. or an m. o. d. inlay, due to shrinkage or something else that seems to prevent it from going to place even though the casting seems to be perfect, it may be due to faulty investing, poor wax technique, or shrinkage of gold. If you will make a staple of clasp-metal gold wire to extend from the mesial into the distal portions of the cavity and build the wax around this staple you will reduce this trouble to a minimum. Inlays made with this reinforcement make stronger anchorages for bridges than those without the staple.—*Pacific Dental Gazette.*

Hutchinson's Teeth.—It has been said that Hutchinson's teeth are pathognomonic of syphilis, but it is not so. You have all had cases of these small pits which run in lines across the teeth, and if you know your anatomy you can tell at just what time the fever occurred in the child. Any eruptive fever, no matter what, will produce an eruption of the skin, and a disturbance of the mucous membrane will be followed by indentations made in the teeth, along their borders or across them, known by surgical writers and syphilographers as Hutchinson's teeth. They are not due to syphilis any more than they are to scarlet fever or any other eruptive disease. They are the result of inflammation which prevented the proper nutrition of the tooth enamel at the time it existed. This statement was indorsed most emphatically by Dr. G. V. Black when I made it many years ago.—TRUMAN W. BROPHY, *Dental Review.*

Lancing the Gums in Difficult Dentition.—I am willing to concede that dentition is more generally normal than otherwise, and that the more aggravated and serious symptoms are, comparatively speaking, seldom met with in children otherwise healthy, and who receive proper care and attention as regards food and surroundings. Still, I believe that

dentition is more frequently the cause of minor pathological conditions than is usually supposed, and, recognizing the serious conditions that may be caused by erupting teeth, I know of no reason for not making the rule to lance in all cases where there is the least possibility or even probability of the pathological conditions of eruption. By lancing, I do not mean scarifying the gums, but deep, thorough cutting down to the tooth. The etiology of this condition is not the pressure of the advancing tooth against the overlying tissue, but the pressure of the jagged unformed roots—which have elongated due to their growth, and have not room to advance because the tissue overlying them has not been proportionately resorbed—back upon the engorged and hypersensitive pulp. Lancing makes it possible for the tooth to advance; the pressure is relieved; pain subsides, and conditions return to the normal. Consequently relief is often afforded even when the tooth is not nearly erupting.—E. A. GULFUSS, *Dental Review.*

Apothesine, the New Local Anesthetic.—Apothesine is the hydrochlorid of gamma-diethyl-amino-propyl cinnamate. It occurs as small white crystals, having a melting-point of 137° C. It is readily soluble in alcohol, slightly soluble in acetone and ether, and very soluble in water. It is quite stable, and will keep indefinitely if reasonably protected from contamination. The solution in water is neutral to litmus. It is precipitated from solution by alkalis and by the ordinary alkaloidal reagents. If desirable, the solution may be sterilized in the usual manner by heating to the boiling-point of water. As is the case with all anesthetics and alkaloids, the best results are insured by the use of freshly prepared solutions. It is supplied in the following forms: H. T. No. 216 (vials of 20 and 100 tablets). Each tablet contains 1½ gr. of apothesine. One tablet dissolved in 60 minims of water—or normal saline solution—makes a 2 per cent. solution (approximately). H. T. No. 217 (vials of 25 and 100 tablets). Each tablet contains ¾ gr. apothesine and ⅓ gr. adrenalin. One tablet dissolved in 60 minims of water—or normal saline solution—makes a 1 per cent. solution of apothesine, in adrenalin 1:30,000 (approximately). This anesthetic is a product of Parke, Davis & Co., and from reports received its toxicity is about the same as novocain, and it has the same resistance to boiling. As a local anesthetic it appears in no way inferior to novocain.—*Texas Dental Journal.*

Dark Areas in the X-ray Film.—Unfortunately many patients have had teeth extracted that could have been saved through scientific dentistry. The reason for the extraction of these teeth was that the dentist was led to believe that the presence of certain dark areas in a dental film was sufficient ground to warrant immediate extraction, thereby removing the primary cause of the systemic condition. This brings me to the interpretation of dental radiographs. Strange as it may seem, the X-ray has been and is much abused. The Roentgen ray was never intended to reveal the exact pathological findings at root-ends. The best that it can do is to aid us in our various tests to draw our conclusions. No man has a right to base his treatment on the reading of an X-ray picture without taking into consideration the various tissue changes that may take place. When men have a true understanding of the tissue changes that take place in acute and chronic inflammation, and are familiar with the histopathology of morbid conditions involving root-ends, then and then only can they realize that the dark area involving root-ends in a radiograph does not always mean a root abscess, or a blind abscess; that the dark area may be nothing more than less density of bone, an epithelial root tumor, a root cyst, an innocent granuloma, a suppurative granuloma, an apical osteitis, osteitis fibrosis cystica, a rarefying apical osteitis, a root-end necrosis, a root-end cementoma, or a proliferative pericementitis. Unless a man has an understanding of these various pathological manifestations he has no moral right to interpret radiographs.—M. N. FEDERSPIEL, *Dental Items of Interest*.

Thorough Mastication as an Economic Measure.—By thorough mastication of food, people would eat much less, get just as much nourishment from the smaller quantity, and avoid frequent digestive disturbances. Mastication is nature's cleansing agent for the teeth, and thorough chewing of the food is an important factor in the maintenance of the dental organs in a condition of health and cleanliness. The teeth, if they are to obtain their proper blood supply, need exercise just as much as any other part of the body.

By thorough mastication, a correct physiological flow of saliva is maintained simultaneously with the ingestion of food, and it is only under such conditions that the salivary secretion is thoroughly incorporated with the food, and thus enabled to properly perform its normal digestive action.

Gum-chewing is but an artificial substitute for mastication. It is a bad habit, causing an abnormal flow of saliva between meals, and if indulged in throws the whole digestive process out of balance.

"Twice the chewing and half the sweets" is a splendid wartime motto for school children. The over-ingestion of sugar in its many different forms—candy, honey, jam, syrups, etc.—has much to do with the alarming prevalence of dental decay. Statistics recently gathered show that while infectious diseases have been materially reduced, there has occurred a marked increase in diseases of the digestive tract, and much of this increase is doubtless due to the "bolting" of food, and over-indulgence in sugar.

Encourage the boys and girls to save teeth, save health, and reduce the high cost of living by the more thorough mastication of food and less indulgence in sweets.—*Oral Health*.

Formulary for Full Upper or Lower Impressions.—The three requisites for a satisfactory impression are (1) areal contact, (2) peripheral bearing of the base-plate, and (3) extension upon yieldable tissue for retention.

Areal contact means contact over the whole area included within the periphery of the base-plate, but does not signify uniform pressure over its whole surface. If the bearing is at the periphery of the base-plate, it will make no practical difference whether there is uniform pressure within the periphery, only so there is contact. If the bearing is at the periphery of the base-plate the artificial denture cannot rock, but if it is at some distance within the periphery there will be rocking and insecure retention.

Areal contact can only be assured by embedding the tissues in a material that flows, one that is neither flexible nor elastic. Thin mixed plaster best serves this purpose.

Peripheral bearing cannot be brought about by a thin mix of plaster alone, but can best be produced by a tray made for the case, or a Britannia metal tray reinforced with pure yellow beeswax, carrying a thin mix of plaster. The thin plaster simply assures contact; the wax secures the required compression over the desired portions of the impression and holds the soft tissues firmly and evenly against their bony foundation. This compression cannot be satisfactorily done by carving either the impression or cast.

Extension for retention is only necessary when the periphery of the base-plate is not supplied with yieldable tissue. For retention the labial and buccal flanges of the base-plate

need only be high enough to exclude ingress of air; however, esthetics may require much extension of the flanges. The essential part of a base-plate to be extended on to yieldable tissue to get retention is the palatal border, from the external portion of one tuberosity to the external surface of the other. The palatal extension upon yieldable tissue should be one-eighth to one-fourth of an inch in width. The palatal extension for retention must hold the soft tissues firmly against its bone foundation, or it will act as a tickler and suggest nausea.—GEO. H. WILSON, *Dental Summary*.

The Perfect Plaster Impression.—*The individual tray:* The first or basal essential in the taking of a perfect impression is a tray suited to the case; in other words, a tray that fits, and from the nature of the work a special tray is necessary to get perfect results.

The S. S. White Impression Tray Compound was devised for the particular purpose of making these individual trays quickly and economically. It is somewhat of the nature of a modeling composition, but with differences that adapt it specially to the making of trays. It is jet-black in color to make it readily distinguishable; has a high melting-point to assure when set or hardened ample rigidity to be self-supporting and to be unyielding when trimmed to a thin edge; and is readily cut as may be desirable in shaping it.

Making the tray: It is necessary in employing the impression tray compound to have a few regular metal trays of suitable forms and sizes. Take a metal tray of the proper shape for the case, but somewhat larger than you would ordinarily use. Fill it with the compound, softening in hot water; a higher heat will be required than in softening ordinary modeling composition. Pass it over a Bunsen or alcohol flame to soften and remove inequalities in the surface and to give it a glaze. Plunge quickly into hot water to wet the surface to prevent it from adhering to the tissues, and as soon as it cools to a bearable degree insert in the mouth, and secure an impression in the regular way. In a short time it can be removed from the mouth and placed in cold water to harden.

Remove the impression from the metal tray, and trim away the compound until you have a thin tray form with the margins about one-eighth inch shorter than the finished outline of the plaster impression is to be. To make sure that there shall be no impingement of the tray form against the soft tissues, and to allow the plaster for the

impression plenty of room to escape freely instead of being forced against the tissues, the inner surface of the periphery should be trimmed to a rather sharp edge. Make sure that you do not trim it too much, as otherwise the plaster when applied in the tray form may not be carried to place—for if it is it will break off because of the long overhang. If you should happen to trim the form too short, the difficulty can be remedied by fusing more of the compound to the form wherever desired, inserting in the mouth while soft, and allowing the tissues of the mouth to properly form the tray outline, which can then be cut down a little to allow for the plaster. Finally score the palatal surface to give the plaster a hold.

We now have a tray that perfectly conforms to and fits the individual case, with no bulky projections or protruding edges to impinge upon and distort the soft tissues or push them from their normal positions.

The impression material: The second essential to the making of a perfect impression is a material of a consistence that will yield without offering the slightest resistance when applied to the delicate soft tissues of the mouth, and then set or harden quickly into a rigid, non-elastic mass bearing the perfect impress of every detail of the surface with which it has been brought into contact. Plaster mixed thin—so thin that it flows—is the ideal material for making impressions. The superiority of plaster as an impression material has always been recognized. The following method shows the way to utilize it to get the ideal results that have been the aim and the despair of prosthodontists from time immemorial.

Getting the perfect impression: Have the patient sit erect in a normal position. This closes the fauces and prevents the plaster from passing down the patient's throat. Mix clean, fine, quick-setting impression plaster so thin that the compound tray when dropped into it—which is the next step—will sink. The plaster should be sifted thoroughly at the time it is used, to be sure that it is freed from any lumps caused by dehydration, as commonly found in plaster. The idea in mixing the plaster to this consistence is to make sure that when placed in the mouth it shall be thin enough to flow readily around and over the soft tissues without disturbing them. Lift out the tray, allow all excess to flow off, insert in the mouth with a rocking motion, and have the patient close the mouth and drop the lips to their normal rest position. Wait a few minutes for the plaster to set before withdrawing. In rare cases

this first impression is all that is required, but usually some parts of the tray form will remain uncovered by the plaster, showing compression of the tissues from imperfections in the shape of the tray form, or because it is too long. Trim all such places away, and make a second trial. Sometimes a third, and rarely, through faulty technique, a fourth trial may have to be made. Whenever the impression fails to be satisfactory, trim away all excess of plaster, thinning down the peripheral edge to provide space or vent to facilitate escape of the plaster, and

thus avoid the stress that would cause the displacement of the soft tissues. Make a new mix of the plaster—very thin—add a little salt to hasten the setting, drop the trimmed tray and impression in the mix, and proceed as before. As often as imperfections appear, trim and try again. The method properly carried out will produce a perfect impression, from which a plate can be made which, because of the accurate adaptation, dispenses with the need for air chambers, suction devices, and the like.—RUPERT E. HALL. *Dental Items of Interest.*

HINTS, QUERIES, AND COMMENTS

Amalgam Restorations for Gold Crowns.

TO THE EDITOR OF THE DENTAL COSMOS:

Sir,—Permit me to offer a few random thoughts with regard to making gold crowns.

Roots to be banded for crowning should always be prepared approxmally and distally according to the Black method for cavity preparation, and in the case of gold crowns the entire root should be restored with amalgam, so as to allow a top thickness of approximately 2 mm., or twice that thickness if the masticating has to be done on a few teeth, or if the gold is to be opposed to porcelain.

In preparing the approximal surfaces at the gum line secure all the space possible, that it may be even greater than the original space when the artificial substitute is inserted.

After the amalgam has fully hardened polish it at the point where it joins with the root. Previous to the amalgam restoration, saturate the root with silver nitrate solution, and before inserting the amalgam tease cement over the cavity, removing it from the margins after beginning the amalgam restoration.

Use seamless bands, and cast the occlusal surfaces of all-gold crowns. When the crown is complete—if of the all-gold variety—trim the band just to the gum line lingually and buccally, but do not allow it to extend to the

gum line between the teeth. The completed crown should be placed on the root and the contact points tested with floss. If these are faulty, they should now be corrected with small pieces of solder properly placed and flowed. Before setting the crown paint the amalgam root-restoration with silver nitrate, and cement in place with a standard copper cement, burnishing the collar to the root carefully before the cement sets. All contiguous crowns should be soldered together.

These methods protect the gums, and make for efficiency. Thus we may earn the gratitude of our patients and ward off the just criticism of hygienists on our incubators of disease germs.

Many molars can be best entirely restored with amalgam, which when properly done is a work of art, and should command a much higher fee than the gold crown, cast or otherwise.

Do not lose sight of the necessity of cutting away the approximal and distal surfaces of bicuspid and molars, no matter how sound, according to the Black method, before crowning. It is the only way in which you can easily gain the necessary space and leave a smooth joint beneath the free margin of the gum at the point where we are most likely to have trouble.

GEORGE E. SMITH.

Byron, Ill.

OBITUARY

Dr. Francis Leroy Satterlee.

DIED, at his home in New York City, Monday, November 12, 1917, in his seventy-first year, after a lingering illness, FRANCIS LEROY SATTERLEE, M.D.

Dr. Satterlee was born in New York City, and was graduated from New York University in the class of 1865, and New York University medical school in 1868. He was a practicing physician in that city for many years, and retired from active work only a month before his death. He was professor of physics, chemistry, and metallurgy in New York College of Dentistry for fifty years, retiring as professor emeritus several months ago.

Dr. Satterlee was police surgeon for nearly eighteen years, retiring as such twenty years ago. He was attending physician at St. Elizabeth's Hospital and consulting physician of the Midnight Mission, and formerly was the attending physician at the Northwestern Dispensary in the department of skin diseases and rheumatism.

He was the author of a treatise on rheumatism and works on gout which were used as text-books in medical colleges. He was an honorary member of the Society of Arts, London; a Fellow of the Academy of Medicine, the Geological Society, the New York Historical Society, and a member of the County Medical Society, the American Medical Association, the Medical Association of Greater New York, and the Pathological Society. He was also a member of the St. Nicholas Society, the Society of Colonial Wars, and the Sons of the American Revolution, and was once president of the Zeta Psi Fraternity.

Dr. Satterlee was married twice. His first wife, whom he married in 1868, died, and in 1906 he married Mrs. Mary Philipse Gouverneur Iselin. He is survived by his widow and two sons, Dr. Francis Leroy Satterlee, Jr., and Major Henry S. Satterlee.

"In Memoriam" Resolutions.

Dr. Frank B. Clarke.

Dr. Frank B. Clarke of Dubuque, Iowa, died October 8, 1917. While seated in his car talking with a friend he was seized with heart trouble, and passed away immediately.

The Dubuque City Dental Society adopted the following resolution:

Whereas, the Supreme Master of the universe, in His infinite wisdom has seen fit to summon to His heavenly home our dearly beloved brother, Frank B. Clarke; therefore be it

RESOLVED, That we, the Dubuque City members of the dental profession and of the Delta Sigma Delta Fraternity, desire to express to the family of our dear brother our most sincere and heartfelt sympathy in their great bereavement. The world has lost a good man, the dental profession has lost an honored member, and our fraternity has lost a beloved brother; and be it

RESOLVED, That these resolutions be published in the DENTAL COSMOS and the *Desmos*, and that a copy be sent to the bereaved family.

H. R. THILL,
R. M. BENN,
Committee.

ARMY AND NAVY DENTAL NEWS

Navy Dental Corps.

NUMEROUS appointments are being made by the Surgeon-general of the Navy to the list of reserve dental surgeons. These appointments are of applicants who are included in the current quota of the selective draft, and are given until December 15th to enter the military-naval service.

Army Dental Corps.

IT WILL be several weeks before it is possible to announce the result of the examination of candidates for appointment to commissions in the Army Dental Corps. Some appointments may be made in advance of the approval of the completed list in order to appoint those who would otherwise be beyond the age limit.

No action has been taken in regard to the promotion of officers of the regular dental corps in accordance with the act of October 6th, several questions of the construction of the law, notably in the matter of the service in grade factor, remaining to be determined.—*Army and Navy Register*.

Regulations Under Selective Service Law Affecting Dental Students.

SECTION 151B of the new selective service regulations concerns especially medical students and hospital interns registered under the law. It became effective December 15th:

"Except in the following cases, no registrant may enlist voluntarily in the military or naval service of the United States.

"Under such regulations as the Surgeon-general may prescribe, and on receiving permission from the Surgeon-general to do so, any medical student, hospital intern, dentist, dental student, veterinarian, or veterinary student may enlist in the Enlisted Reserve corps of the Medical department, and thereafter on presentation by the registrant to his local board of a certificate of a commissioned officer of the Medical department of the army that he has been so enlisted, such certificate shall be filed with the questionnaire, and the registrant shall be placed in Class V, on the ground that he is in the military service of the United States. There is no other ground

on which such persons (as such) may be placed in a deferred classification."

The effect of classification in Class V is to exempt or discharge from the draft. Regulations to carry out these paragraphs will be issued by the Surgeon-general. The effect of the new regulations will be to extend to first-year medical students, after December 15, 1917, essentially the same privileges in respect to army service as are now enjoyed by students of the second, third, and fourth-year classes. The approval of the Surgeon-general will be granted to such students in well-recognized medical schools only.

Since, under existing conditions, it is extremely unlikely that further calls for the present draft will be made before December 15th, the fear expressed by first-year medical students that they may not be able to continue their medical course is unwarranted, if they have not already been cited for the draft by their local board. In that case the Medical department has no authority—*Journal of the American Medical Association*.

Assignments.

Army Dental Corps.

Week ending November 24th.

1st Lieut. George Krakow, now on temporary duty with 35th Engineers, Camp Grant, Ill., assigned to permanent duty with that regiment.

Army Dental Reserve Corps.

Week ending November 24th.

1st Lieut. Albert Mehrer to Fort Sloeum for duty.

The following to Chicago, School of Plastic and Oral Surgery, Northwestern University Dental School, for instruction: 1st Lieuts. Jack W. Seherer, James V. Sparks, Frank S. Leonard, Floyd D. Leach, Earl T. Young, Sherman M. Fowler, Max C. Frazier, Donald M. Gallie, Jay H. Lee, Brien B. O'Bannon, Merton M. Postle, John Voss, Everett E. MacGibbon, Walter McN. Morgan, and George D. Siewert.

1st Lieut. Alexander W. McClean to Fort Worth, Camp Bowie, for duty.

1st Lieut. Charles Steffens to School of Plastic and Oral Surgery, Northwestern Uni-

versity Dental School, Chicago, for instruction and return to station.

The following to Camp Wheeler, Ga., for duty: 1st Lieuts. Deazil C. Barnhill, Clifton E. Donnell, and Ira D. Funkhauser.

Week ending December 8th.

Francis R. Steirly to Camp Fremont, Cal., for duty.

1st Lieuts. Louie T. Austin and Ray D. Curry to Presidio of San Francisco, Cal., for duty.

1st Lieuts. Fay T. Brown, Norman C.

Spencer, and Harold A. Stone to Garden City, N. Y., concentration camp and supply depot, for duty.

1st Lieut. Hervé C. Manon to 30th Engineers, Camp American University, for duty.

The following first lieutenants to places for duty: Leroy C. Andersen to Camp Lawrence J. Hearne, Cal., and Magnus A. Gerde to Fort Barry, Cal.

1st Lieut. Alphonse L. Senecal to Philadelphia, School of Plastic and Oral Surgery, Evans Dental Institute, for instruction, and to Fort Slocum for duty.

To Every American Dentist.

By J. W. BEACH, *Chairman*, Buffalo, N. Y.

President Wilson has asked that every resource for winning the war be utilized to the very limit. The dental profession forms one of the greatest resources for making our army efficient. You are an integral part of this great source of help to your country. Will you meet this responsibility as an American citizen should? Of course you will!

How CAN IT BEST BE DONE?

Join the League *now*, and assist in its great work. Ten thousand new members are needed right away. If you are already a member, we ask you to get at least five more as soon as possible. The mouths of the men in our new national army must be made healthy and dentally fit before going to cantonment, and we must help to the limit of our ability.

The Preparedness League of American Dentists is a recognized agency for carrying on this work under the direction of the Surgeon-general's office, the National Dental Association, and the Committee on Dentistry, subcommittee of the Council of National Defense.

There are forty-five thousand dentists in the United States. Six thousand belong to the League, and have done the major part of the following work: July 16 to November 3, 1917: Fillings 60,946; extractions 35,909; cleanings 2,233; crowns 133; bridges 184; plates 165; unclassified operations 6,891—total 111,061. Thousands of operations not listed were performed prior to and since these dates.

If every one of the 45,000 had done his part, what a splendid showing we could have made. It is not too late to become a part of this great work for increasing the fighting power of our army. We know you are with us.

Don't let the Germans show all the efficiency! Let's show what we can do!

We've got to work together to win this war. Do your part by joining the League *today*, and we will give you real, properly directed work to do.

For membership send one dollar (\$1.00), payable but once, to the Preparedness League of American Dentists, 131 Allen st., Buffalo, N. Y. (Kindly inclose business card to avoid mistakes in name and address.)

SOCIETY NOTES AND ANNOUNCEMENTS

NOTICES should reach the Office of the DENTAL COSMOS *not later than the 11th or 12th of the month preceding that of publication.*

American Institute of Dental Teachers.

THE next annual meeting of the American Institute of Dental Teachers will be held at Hotel Schenley, Pittsburgh, Pa., January 29, 30, and 31, 1918. The meeting as usual will be devoted to dental teaching. A number of the papers will deal with situations arising from war conditions. A cordial invitation is extended to all interested in dental teaching.

ABRAM HOFFMAN, *Sec'y*,
381 Linwood ave., Buffalo, N. Y.

Chicago Dental Society.

THE annual Clinic of the Chicago Dental Society will be held in the LaSalle Hotel, Chicago, Ill., January 26, 1918. The program promises to be one of special interest to the profession. Remember the date.

P. B. D. IDLER, *President*.
T. A. BROADBENT, *Sec'y*.

University of Iowa, College of Dentistry.

THE dedication of the new dental building of the College of Dentistry, State University of Iowa, will be held February 22d; the Alumni and College of Dentistry Clinic, February 23, 1918, in Iowa City, Iowa.

R. R. DEKRUIF, *Sec'y*,
Des Moines, Ia.

Minnesota State Dental Association.

THE thirty-fifth annual convention of the Minnesota State Dental Association will be held February 7, 8, and 9, 1918, at the University of Minnesota, Minneapolis, Minn.

All members of the National Dental Association are invited. For information, write

MAX E. ERNST, *Sec'y*,
1125 Lowry Bldg., St. Paul, Minn.

Connecticut State Dental Association.

THE fifty-fourth annual meeting of the Connecticut State Dental Association will be held at the Hotel Taft, New Haven, Conn., April 18, 19, and 20, 1918.

GEO. S. B. LEONARD, *Sec'y*.

Virginia State Dental Association.

THE Virginia State Dental Association will meet in Roanoke, Va., April 25, 26, and 27, 1918.

F. R. TALLEY, *Corr. Sec'y*,
Petersburg, Va.

North Carolina Dental Society.

THE North Carolina Dental Society will meet on June 19 to 21, 1918. Headquarters, Oceanic Hotel, Wilmington, N. C.

W. T. MARTIN, *Sec'y*.

North Carolina Board of Examiners.

THE next meeting of the North Carolina State Board of Dental Examiners will be held at Raleigh, N. C., beginning at 9 o'clock on Thursday morning, January 10, 1918. For further information and application blanks address

F. L. HUNT, *Sec'y*,
Asheville, N. C.

Montana Board of Examiners.

THE Montana State Board of Dental Examiners will meet in Helena, Mont., January 14, 15, 16, 17, and 18, for the purpose of conducting examinations. Applications should be in the hands of the secretary not later than January 1, 1918.

G. A. CHEVIGNY, *Sec'y*,
107 Clark Block, Butte, Mont.

Idaho Board of Examiners.

THE Idaho State Board of Dental Examiners will hold their next session in Boise, Idaho, January 14 to 17, 1918. Address

A. M. JACOBSEN, *Sec'y*,
255 E. Center st., Pocatello, Idaho.

North Dakota Board of Examiners.

THE next regular meeting of the North Dakota Board of Dental Examiners will be held in Fargo, N. D., beginning Tuesday morning, January 8, 1918. All applications and credentials should be in the hands of the secretary ten days prior to the date of examination. For application blanks and further information, write to

W. E. HOCKING, *Sec'y*,
Devil's Lake, N. D.

South Dakota Board of Examiners.

THE South Dakota State Board of Dental Examiners will hold its next examination at Sioux Falls, S. D., beginning January 7, 1918. All applications must be in the hands of the secretary by January 1st. Fee \$25. Address

ROBERT JASMANN, *Sec'y*, Scotland, S. D.

Massachusetts Board of Examiners.

A MEETING of the Massachusetts Board of Dental Examiners will be held in Boston, Mass., February 11 to 15, inclusive, 1918, for the examination of candidates for registration. All applications must be in the hands of the secretary on or before February 2d. For further information address

GEORGE H. PAYNE, *Sec'y*,
29 Commonwealth ave., Boston, Mass.

ORIGINAL COMMUNICATIONS

Impacted Lower Third Molars.

By C. EDMUND KELLS, D.D.S., New Orleans, La.

[Copyright 1918.]

THE removal of impacted lower third molars appears to be of more than passing interest to the profession generally, as evidence by the fact that such an operation is often the leading card at dental clinics, that papers upon the subject appear in our journals from time to time, and, moreover, from the fact that such cases are quite frequently met with in general practice. There appear to be two methods of removing these teeth:

(1) One in which the patient's jaw is chiseled away to such an extent that the tooth may be taken out whole, ether or novocain being used, according to the fancy of the individual operator. By whom this heroic operation was originated I am not prepared to say.

(2) The one in which the tooth itself is cut in two under novocain. The patient's jaw is handled gently, and the tissues surrounding the tooth are injured but slightly. This operation was originated by the writer and was first described before the National Dental Association in 1903.

It is hardly possible to witness the removal of these teeth by the heroic mallet-and-chisel method, to hear the resounding blows of the mallet, and not feel compassion for the patient.

The writer has attended several clinics where clinicians of national repute removed such teeth by this mallet-and-chisel method. In every case, however simple—and some of the cases were *extremely* simple—the patients were put “out of commission” for days, suffered for many days longer, and the wounds (for wounds really were made) were treated for several weeks thereafter. Where the operator took the operation more seriously and used ether, the patient spent one day before and several days after the operation in the hospital, making an average of from five to seven days, several of which were in bed.

Just imagine, if you can, what the total cost of such an operation would be to a patient—one day in bed before the operation and five days after; seven days' hospital charges, besides those of the chief operator, the anesthetist, and three

or four assistants! If a charity patient, what a burden upon those who "paid the freight"!

So much for the mallet-and-chisel method, with its mutilation of the patient and the consequent train of suffering, treatment, and expense.

Under the writer's method, the tooth itself is cut in two, as already stated, from one to two-thirds of the crown being cut away, according to the case, whereupon the released part of the crown is readily removed. The root portion is then grasped by special forceps designed for the purpose, and *drawn forward* into the space left vacant by the removal of the portion of the crown which has been cut away.

inflammation of the throat, with discomfort and pain in that region, and in these cases the throat receives treatment; but even in these the sockets themselves have always looked well and have *received no attention whatever*. At other times, in very difficult cases, there is some swelling of the face, and the mouth cannot be opened freely; again these symptoms are treated, but the socket looks well and receives no attention.

TOOTH FORMS.

The writer has extracted scores and scores of lower third molars which were *standing vertically*, and which had all manner of roots (see Fig. 1), but he has

FIG. 1.

Once the root has been started from its socket and drawn forward, there is always ample space for its ready removal. It will be seen that by this operation little or no injury has been done to the soft tissues and surrounding or overlapping bone or process, and thus it is not surprising that little or no after-pain ensues, and no subsequent treatment is necessary.

Sometimes an elevator specially adapted to such work is used to start the root. Sometimes, in particularly difficult cases, a little of the process must be *burred away* in order to get the beaks of the forceps on the root.

It is not unusual for a patient to come from the country in the morning, have such a tooth removed, and leave for home the same day. The sockets are *never curetted or packed*; possibly that is why they require no treatment. Sometimes there is a certain amount of in-

never yet met, in his own practice, any impacted teeth of such shapes. In Fig. 2 are shown typical forms of impacted teeth. Their roots are all more or less straight and are of a distinctly different class from those shown in Fig. 1.

The question naturally arises, are these simply the vagaries of his individual practice, is it coincidence, or have other operators met with the same experience? It certainly would be interesting to know, and if perchance the experience of others has been the same, then for once Providence has been somewhat kind.

INDICATION FOR THE AUTHOR'S OPERATION.

The writer's operation is only indicated where the third molar is really *impacted*, that is, when it lies more or less horizontally and is prevented from

erupting by its relative position to the second molar.

SPECIAL FORCEPS.

As far as the writer knows, every pair of extracting forceps now cataloged was

FIG. 2.

designed for grasping teeth standing in a perpendicular position.

In the early days of this operation, after the part of the crown of the impacted third molar was cut off, the root was removed with an elevator. The use of an elevator, however, is a harsh procedure, especially in such cases as those under consideration, and so the idea was conceived of making a special pair of forceps with which to grasp the remain-

ing portion of the tooth and draw it forward, thus materially lessening the trauma.

Fortunately, a pair of Ash's forceps was found which, with only a slight alteration, made an ideal instrument for this purpose, and undoubtedly by its use the trauma has been materially lessened in every case. Fig. 3 shows how a typical impacted third molar can be firmly grasped by these forceps. In deeply embedded molars it is necessary to bur away the process to allow the beaks to be forced into position.

In a recent number of the *DENTAL COSMOS* a writer upon the subject has illustrations showing how he cut off the cusps of *some* of these molars with disks, advancing the method as new. This shows, of course, his unfamiliarity with the literature upon the subject, as the idea of cutting off the cusp was first published in 1903, as previously stated, once or twice since, and is fully treated in the third edition of Johnson's "Text-book of Operative Dentistry," though, of course, the cutting is not done with disks, as the use of disks for the purpose is almost impossible. It is possible, of course, to cut away the cusps of well-exposed teeth by means of disks, but it never should be so done. The unerupted portion of the crown is covered upon two sides by gum tissue, and possibly some process. The disk must therefore cut gum, process, and all, lacerate the parts fearfully, and play havoc generally!

When it comes to deep-seated molars, the lower edge of the tooth which must be cut away may be fully three-quarters of an inch below the top of the second molar. In order to reach this depth the disk must be over *one and a half inches* in diameter. Just get a disk of that diameter, mount it, put it in the engine handpiece, and adjust it back of a second molar, and see how impossible it would be to use it!

The writer does all of the deep cutting with burs made specially for the purpose. In favorable cases he may start with a short bur, but the burs must be extra long to reach to the depths often required. (Fig. 4.)

The enamel is first nicked with a carborundum stone in order to allow the burs to get a start. The contra-angle handpiece is held horizontally above and about parallel with the tops of the

A saliva tube is placed in the opposite side of the mouth, while an assistant keeps the operative field absolutely free from saliva, mucus, and blood by means of a suitable "tip" connected to an

FIG. 3.

The beaks of these forceps have been ground out so that they are somewhat similar to those of the well-known "Kells" forceps, which were first made by the writer's father some forty or more years ago. The bulge of the crown fits into the hollow beak, so that the beak does not slip off. When the tooth shown in the illustration was grasped by these forceps for removal, the beaks did not protrude beyond the tooth as shown, but were forced down only as far as the surrounding process would allow them to go, and *yet* they secured a firm hold upon the tooth. The tooth was drawn straight forward in the line of its long axis, and thus very little strain was made upon the surrounding process. The tooth was twisted and rotated slightly in order to start it from the socket, just as would be done in extracting a vertical tooth.

molars, and rotated so as to swing the bur possibly from twenty to thirty degrees to each side of vertical, and an up-and-down, sawing motion is also given to the bur. In this manner, the operative field is limited to the space from

aspirating machine. Frequently, not a single "sponge" need be used. By this method much time is saved, the patient swallows no blood or mucus, and the work proceeds at a minimum of discomfort and maximum of speed.

Just imagine for the moment a dentist himself with such an impacted molar! On the one hand, he can have it removed absolutely painlessly in the manner just described, lose a few hours, all told, from his office, and no after-treatment. Or, he can have it chiseled out under novocain, undoubtedly lose from one to several days, and have the socket packed for weeks. Or, he can take a general anesthetic and have it removed by the mallet-and-chisel method, spend a goodly number of days in a hospital, losing that many from his office, and have the socket packed and treated for several weeks

FIG. 4.

which the overlying gum and process have been removed. The gum and process upon the lingual and buccal sides of the tooth are encroached upon but slightly, if at all. Consequently, there is but little laceration of the parts and but little loss of blood.

thereafter. With the choice of these three evils, it is not difficult to decide which one he would choose for himself; then why not make the same selection for his patients?

INFECTION.

A volume might be written upon the subject of infection, and the writer is assured in advance of severe criticism of his ideas of oral infection, but it will be noted that these criticisms only come from those who cling to practices of the past, who have not tried his methods, and therefore are in no way capable of judging of his results. Facts, like mules, are stubborn things, and the patients themselves are incontrovertible evidences of the soundness of his methods.

While some of the leading oral surgeons and clinicians of the day curet and pack the socket after removal of the impacted tooth, what have they to show for it? Only suffering and discomfort, inconvenience and expense!

MODERN SURGICAL PRACTICE.

It is an assured fact that the better class of general surgeons are getting farther and farther away from *drains and packings*. Twenty-five years ago, ninety-five per cent. of clean abdominal operations were drained. Today, unless there is considerable oozing or strong suspicion of active infection, no drains are used. Whenever a drainage-tube is used, the natural exudate is constantly interfered with by the irritating action of the tube, and therefore the period of healing is prolonged.

Of late years the general surgeon, that is, the more observing general surgeon, has come to realize that the less he does after the operation to interfere with the natural processes of repair, the better it is for the patient.

When the writer discontinued the packing of sockets, many years ago, he still considered it necessary to wash out the wound from day to day with an antiseptic solution, and devised an apparatus for doing this, but for several years past this also has been absolutely discon-

tinued, upon the principle that the less we do for that socket after a nice clean surgical operation has been performed, the better it is for the patient, and the results obtained prove the theory to be correct.

CHARACTER OF CLIENTÈLE AS A POSSIBLE FACTOR.

Possibly the character of the practice bears some relation to the possibility of infection. It must be admitted that all of the writer's experience has been with the better class of patients, and thus he deals practically only with rather clean mouths, pretty well taken care of.

Possibly patients in a charity clinic might not make such a favorable showing, and in that case he can conceive that even with his operation the daily flushing of the socket with warm saline solution might be advantageous for a week or so, though he doubts it. But as for packing, Never!

NATURE'S METHOD OF CARING FOR WOUNDS CAUSED BY EXTRACTION.

Let us now consider what occurs after the extraction of a tooth when nature is given a chance. First, hemorrhage occurs and then the socket is immediately flooded with saliva—saliva possibly carrying some pathogenic organisms.

A blood-clot is formed in the socket and some active ferment is at once formed in the tissues practically in contact with the blood-clot, and this successfully combats the organisms carried in the saliva. An exudate is thrown out, and under these circumstances healing takes place rapidly.

SURGICAL INTERFERENCE.

On the other hand, a tooth is removed, whereupon blood flows and the socket is again flooded with saliva. But not contented with nature's way, the socket is curetted and packed with gauze. Or, possibly, it is just packed with gauze without being curetted.

Under these adverse conditions, does

nature just "throw up the sponge" and quit, and leave it all to the surgeon? Not at all; she still does the best she can to overcome his errors, and starts the ferment, the exudate, and the process of healing. Next day comes the operator, who removes the packing, which process simply tears to pieces the work of healing which nature has been doing during the previous twenty-four hours. Then he re-packs the wound, only to repeat the destructive process next day.

USE OF IODIN IN THE SOCKET CONTRA-INDICATED.

Possibly the socket is swabbed with iodine. Now, what does that mean? One of two things: (1) If the socket has not been effectively dried (which usually is impossible) and iodine is applied to the wet surface, it is absolutely ineffective—just so much time and iodine wasted; and (2) If it were possible to thoroughly dry this surface and apply the tincture of iodine to it, then iodine, being destructive to such a new growth as is found in a healing socket, does it more harm than good, and consequently, better results and quicker healing would be expected without its use.

However, as a matter of fact, it being practically impossible to dry these surfaces, the iodine does not do very much harm after all. And so this continues for days and weeks! A large portion of what nature accomplishes during twenty-four or forty-eight hours is quickly destroyed by the removal of the dressings. And what have the dressings accomplished? Merely a prolongation of the period of healing.

A truthful verdict upon the procedure would probably read, "The socket gets well in spite of the operator, instead of on account of him."

CHARACTER OF THE BONY STRUCTURES.

If a section be made through the bony socket of the impacted molar, it will be observed that the portion of the bone covered by the periosteum is very dense and *very smooth*, while all the bony

structure within and protected by this external smooth plate is not only porous, but exceedingly so.

Under the writer's operation, very little of this dense external plate is interfered with, and consequently the bone itself is left in the very best condition for prompt healing. Under the mallet-and-chisel operation a large block of this external oblique line is cut away and a large surface of the porous bone is left exposed, and, from its very nature, possibly invites infection and its consequent train of troubles.

CLIMATIC EFFECTS.

The writer spends a good part of his annual vacations in visiting hospitals, clinics, and his professional friends in their own offices, all in eastern and western cities. Long ago he concluded from what was seen upon these visits as compared with what he saw in his own office, that oral infections, even after ordinary extractions, were much more common in northern latitudes than in the south. The more he traveled and the more he practiced in his home city, the more he was convinced of this fact, but now he has changed his mind upon this point completely!

Is it a coincidence that all of this infection which follows tooth extraction which he has seen in the northern cities occurred in cases which were treated and *packed*? Or was the infection due to the packing and treatment?

One of the reasons the general surgeon—the progressive one to whom reference has already been made—has given up packings, is because he found that he occasionally reinfected his sterile wound by his packings.

THE TIME FACTOR.

It is admitted that the writer's operation, as practiced, is a somewhat lengthy one, but it is claimed that it is *humane*.

THE HUMAN FACTOR.

Simply because the method of removing such a molar by the mallet and chisel

is quick and comparatively easy, should such a method necessarily be employed? Again, simply because the writer's method is not quick and easy, but requires much more time and is much more difficult for the operator, should it be condemned? Should not the welfare of the patient be the paramount issue?

THE PRECEDENT OF GENERAL PRACTICE.

Just because a method is "general practice" does not necessarily make it correct practice. Some man of note "starts something"; it looks good and is apparently successful, and thus soon becomes general practice. After a while, possibly someone else, equally as prominent, brings out a much better method, and the most progressive men adopt it, and so what was general practice once upon a time is now only practiced by a few.

Under this rule, general surgery has undergone radical changes within the past few years, and it has been shown that some of these changes in general surgery were worked out independently by the writer in his operation for the removal of impacted third molars. Of late, a number of operators have adopted this operation, and undoubtedly, in the not distant future, all who have the best interests of their patients at heart will be compelled to give up the mallet and chisel, and also either adopt this method or devise one equally good—perhaps better—and get in line with modern surgical practice, discard the gauze packings, discontinue the disturbance of the socket, and give up using iodine where it is entirely ineffective.

1237 MAISON BLANCHE.

A SPECIAL CASE CITED.

Fig. 5 illustrates a fine example of a vertical third molar which never erupted, and yet as the result of infection had closed the patient's mouth for a week before she called. The trismus was treated and reduced, and as soon as the region became accessible, the offending tooth was detected with the aid of the skiagraph, and extracted.

Fig. 5.

Notwithstanding the previous record, no curetting, packing, or washing of the socket followed, healing progressed rapidly, and the patient is not only still very much alive—two years later—but as fine a specimen of womanhood as one ever would want to see.

It would probably be difficult to find a better case than this one to illustrate the value of *no after-treatment* in these cases. An impression was taken before the extraction of the tooth, and after the model was poured the extracted tooth was set in the model in the position it held in the jaw.

Type *vs.* Temperament in the Selection of Teeth.

(IV.)

By NORMAN S. ESSIG, D.D.S., Philadelphia, Pa.

(Read before the monthly meeting of the Pennsylvania Association of Dental Surgeons, Philadelphia, December 11, 1917.)

THE subject about which I shall speak tonight has so long impressed me as being one of very large proportions that I am unwilling to concede that any other phase of dentistry exceeds it in importance.

I have the honor this evening to address the Pennsylvania Association of Dental Surgeons, yet I am constrained to believe that most of you are in general practice, and that many of you are at least occasionally required to perform a service in prosthesis. To be interested in but a portion of a subject is not to be interested at all, but to be interested in any subject in its entirety is to love it and find an interest in all its details.

I am bringing to you tonight, as a result of my own interest, an enthusiasm with which I hope to infect every man present; and to that end I have assembled certain facts, and evolved methods pertinent to them, to which I shall direct your attention.

It is a well-known fact that in prehistoric man, and through all subsequent periods of which we have any knowledge, there have existed at least three fundamental basal types of tooth form to which all others may be related and classified. The dentist, however, has made little use of these facts other than to accept them with reservation, and has continued to take what he could find in the way of artificial substitutes without availing himself of the practical helpfulness of a knowledge of these basal considerations now easily within his reach.

The study of the anatomy and physiology of human teeth, and the selection and adaptation of porcelain substitutes with reference to the restoration or creation of a temperamental harmony, which all true dental prosthesis embodies, is a part of our field of study as dentists that we can ill afford to neglect. To pass over this lightly is more than a neglect of duty to dentistry itself; it is to debase prosthesis by allowing that department to fall into the hands of the mere mechanic, who is in no way equipped or competent to render anything beyond a purely mechanical service.

I do not intend to offend or to detract from the importance of the skilled mechanic, but dentistry cannot be practiced by correspondence, nor is it reasonable to expect the highest esthetic attainment in a prosthetic restoration from one who has never seen the patient. The hope of creating a demand for better things in dental prosthesis by placing the subject in a comparatively new light is uppermost in my mind.

The discussion of "type *vs.* temperament" has always divided the point of view of the profession to such an extent that it has impeded progress along the lines of so-called "mechanical dentistry," and furthermore, it has prevented the subject from being taught from any definitely established standpoint. Consequently, I have assumed a rôle requiring some resolution and courage on my part, in that I shall endeavor to bring all parties together on the ground that the

difference is in appearance and not in reality, a difference of nomenclature only, and that the word "temperamental" applies only to the effect obtained by the judicious selection and application of true types or their modifications.

In recalling discussions upon the subject I have been convinced that the dental profession is less interested in theories along prosthetic lines than it is in facts practically systematized to their advantage and so placed before the practitioner as will enable him to make practical use of them in a systematic and rational way.

The existence of the basal types is so thoroughly an established scientific fact that argument upon that point at this date would be a waste of time. See writings of Williams and of the writer.*

The establishment of the basal types has done much to simplify matters, for as there are three prime forms as a basis for typal classification, it must also of necessity be the foundation for the temperamental theory as herein previously defined; consequently, those who once differed vehemently may now select their artificial teeth from the same assortment, and any remaining differences may be explained by the fact that the eruption and development of the teeth of the human race is from a practical viewpoint entirely arbitrary, as a result of the unrestricted interbreeding of human types, and teeth therefore become a law unto themselves. Consequently, as far as the dental profession is concerned in matters pertaining to the selection of artificial teeth, the term "temperamental" may be limited to express the result attained by the judicious arrangement and application of the basal types. Moreover, these types in nature, as progressively and automatically rearranged in the mouth of man by wear, by characteristic habitual mental traits, physical limitations, and changes due to the loss of other teeth, necessarily ex-

press characteristic temperamental harmony, or so-called temperament.

The policy which I have adopted in practice is to use as standards for the three fundamental types the strongest and most characteristic examples of each, and make suitable modifications expressive of crossings or composites to suit my purpose by changing the contour lines at certain definite points by grinding.

After carefully viewing the subject from its several angles we must eventually reach a point where we begin to discover the system or order involved in the sequence of events, which not only throws additional light on the principles underlying the question of selection, but also enables us to systematize the process and to clearly and definitely outline a policy which demonstrates its practical value, and at the same time illustrates the importance of the personal factor when methodically applied in prosthetic dentistry.

He who elects to study dentistry doubtless does so because he imagines he is by nature endowed with talents of a kind that will lead eventually to a measure of success in the practice of his chosen profession. During his collegiate preparation or the pre-graduate period an absolute failure in any one branch or department will preclude the possibility of his graduation; so also will the absence of the factor of personal fitness or adaptation to the requirements of his calling cause an absolute failure in the subsequent or post-graduate career of the student of dentistry; for one must ever be a student, and in consequence of the absence of this quality of natural or acquired fitness for the practice, we continually meet with examples of prosthetic dentistry which shock and outrage every artistic sense, even before the observer is near enough to determine whether or not there is any technical merit in evidence in the case.

It is to this end the writer has devoted time and thought in the past with the hope that an influence for the betterment of dental prosthetics might be brought to bear upon those on whose

* See, *e.g.*, my three former articles on "Type vs. Temperament in the Selection of Teeth," *DENTAL COSMOS*, 1917, vol. ix, pp. (I) 879, (II) 1110, and (III) 1218.

The Three Basal Types.

TYPE III.

Showing, in porcelain teeth, the three fundamental basal types, which are used as the basis for subsequent modification.

shoulders rests the burden of teaching the subject. He has therefore endeavored to systematize the solution of certain problems, and to lay before the profession his interpretation of the question of selection and artistic restoration in dentistry.

It is to be assumed that many, if not all, of the preliminary steps in the technique of mechanical dentistry have been adequately conventionalized and reduced to a system of sufficient simplicity and uniformity to enable those teaching the subject, throughout this country at least, to instruct the student along lines which are reasonably uniform, but it yet remains for the esthetic side to be as thoroughly and systematically taught with the idea of cultivating a broader conception of its importance and a larger development of the personal side of the question in the case of the individual practitioner. This can best be done when we have realized certain facts

which, in the opinion of the author, are firmly established. These are of sufficient importance to be a tremendous factor in obtaining results which every man who has the welfare of his patients at heart should strive to achieve.

We as a profession must realize that there are important personal touches which must be the handiwork of, and cannot be neglected by, the individual responsible for directing the case in prosthesis. These can under no circumstances be done in the laboratory without reducing the result to the plane of a mere mechanical production, representing no more or no less than precision in finger skill, but absolutely lacking in character and artistic value.

The public must also be enlightened on the higher possibilities of dental art, and made aware that there are possibilities unlimited in this direction; that the production of an artistic prosthetic restoration is one of the highest progressive

attainment, and not a mere mechanical service. They must be made to under-

stand that everyone owes something to his fellow man, and that no one has a right to shock the sensibilities of those about him by appearing in public or among his friends marred or modified in appearance by inadequate or inappropriate dental restoration.

Were we at all times provided with models of the original dentures, or if

certain basal types of teeth were inevitably found in certain types of countenance, the task would be a simple one indeed; but as this is not so, the problem must be solved by other means—at least from the standpoint of selection.

After having fixed firmly in our minds the three basal types, and all that they mean as a basis of classification in the

study of the comparative anatomy of the teeth of human beings, harmony of outline should be the first consideration in

the selection of artificial teeth, as the size will be guided by the proportions of the arch and the proximity of the upper and lower jaws. To determine and obtain the lines of harmony, the plan or policy is to select a portion of the face having a characteristic bilateral symmetry, at a point nearest the teeth themselves;—obviously, from that portion bounded above by the eyebrows to a line drawn horizontally across the face through the commissure of the mouth at right angles with the median line drawn from a point between the brows, dividing the face in halves by bisecting through the nose and mouth. It will be found that the outlines confined within these measurements, embracing the most characteristically expressive facial area, will suggest the outline for the selection of artificial incisor teeth which will properly harmonize with the general outlines of the face. (See DENTAL COSMOS for November 1917, vol. lix, p. 1115.)

If the patient has a full, broad countenance with high cheek-bones, a full, broad tooth of a comparatively pure type is suggested; while, on the other hand, if the face falls away or is modified in other ways, the selection should be modified in outline and profile to suit the case in hand.

The full face suggests the general outline, while the profile of the tooth should represent the modification and profile of the countenance, to be harmonious.

In the three pure or basal types we have the best means of harmonious restoration, because the logical changes can be made by the operator who must design the alignment and articulation. If the result is to be one of artistic merit he must do this part of the operation with his own hands.

The form and outline of the basal types, in a given case, for the central incisors having been established definitely, attention is bestowed upon the laterals, which we find are a "law unto themselves" even to a greater degree than any other of the six anterior teeth, a peculiarity naturally attributed to certain influences which govern their surroundings during development, while

augmenting or curtailing such development according to the room allotted them while the capsule is soft and yielding. This produces great variation in natural normal mouths, and will allow the prosthetist to take liberties of a similar nature which are entirely within the limits prescribed by natural conditions.

That temperamental harmony can be obtained by this treatment of the lateral incisors there can be no doubt, but the incisors are incomplete without the cuspids, which give finish and character to both the function and the outline of the anterior teeth, which from the esthetic standpoint must be regarded as a unit in conformity and symmetry. These teeth should be draped with skill and judgment on each side of the median line, maintaining the harmony produced by the central incisors; the space between being completely filled by the laterals, whose general conformation should be in keeping, as has already been shown, with the room allotted to them.

Modification or digression from type is easily and readily attained by slight grinding at certain important points so that crossings and modified types of a much more appropriate nature can be thus produced than by selection from the manufacturer's stock.

Wherever there are natural teeth alongside of which artificial substitutes are to be placed, our opportunity for securing harmony and precision are much greater if we modify the basal type of artificial tooth to suit the case.

Where the patient is edentulous and there is no model of the natural teeth to guide, such modification is necessary in order to produce the required harmonious discord and a reproduction of those accidents of nature which are so cunningly interdependent that the lines individually and collectively fall away, together with that degree of concord whereby no one feature is given undue prominence.

It must be admitted, however, that there is a need of modification or crossings, and a limited stock of these modified typical forms is desirable from the

standpoint both of the dentist and that of the manufacturer, but the more the dentist relies upon his own ability to create such crossings in special cases the greater will be the artistic development along these lines among the members of the dental profession. For whatever is done to break up regularity in form or shade, it will be found that the improvement is vastly out of proportion to the effort expended.

It will not be advisable or necessary at all times to change the buccal or labial surfaces of the artificial teeth, as many of the modifications which are frequently seen in natural teeth have their greatest variation from type expressed upon the approximal surfaces.

It has also been shown that an automatic readjustment takes place from the time when the permanent tooth is erupted, and that characteristic identity is largely brought about by what may be designated as the different stages of wear, which gradually modifies the general form of teeth as well as the conformation of their occlusal surfaces.

Color and shade must ever remain a matter of artistic judgment, though a dependable guide may be established by using as a basis of consideration the fact that in youth and comparative youth teeth are less dense, and consequently of a lighter shade, and each succeeding year the dentin ordinarily becomes more dense, with a consequent deepening of the shade toward a bone-like yellow.

The frailer organs of mastication and those which have never been strong will be found to have a lighter hue, which often has a bluish cast. There are other dark shades which, however, are often the result of some other influence, such as deposits of extraneous matter which interfere with the transmission of light; this can be imitated by means of mineral stains, the use of which will enable the operator to reproduce the appearance of nature with great accuracy, though it may be assumed that the general color of artificial teeth should be representative of health and vitality, modified by the age of the patient.

It is not possible to anticipate the form and shade of the teeth of mankind with a reasonable degree of accuracy by studying the different faces we meet daily on the street or in places where men gather. This the writer has proved to his satisfaction by repeated trials, with the result that the careful scrutiny of a face with this idea in view has become habitual. The cases, however, where there is found to be ideal harmony between the outline of the teeth and that of the face are rare indeed, and keen disappointment is often in store where the smile or conversation reveals the organs of mastication. We are all able, however, to anticipate with great accuracy the fact that an artificial denture is worn; especially is this the case in the upper mouth, and, except in rare instances where care and skill have been expended to compensate for shrinkage, due to the absorption of the alveolar walls after extraction, a peculiar blank or characteristic expression of the upper lip takes place which apparently influences the position of the nose. This is in large part due to the maladjustment of the canine protuberance. The extraction of the canine teeth will effect a greater change in the appearance of a man or woman than the loss of any other teeth in the dental arch; yet it would seem that comparatively little importance is attached to their proper and intelligent placement by those whose duty it is to assume the responsibility of the

personal appearance of those who require a service of that character.

The types of artificial teeth having a bold profile are sadly lacking, especially in the No. III type, and it is often impossible to obtain such teeth at all, whereas many faces demand this type in order that the normal expression may be restored.

Our attention is often attracted to the fact that the artificial incisors are too prominent, or that there is a peculiar recession which is in reality due to the lack of profile, and a predominance of straight lines. This renders it impossible to obtain certain natural effects, both in the adjustment upon the ridge and in the rotation of individual teeth to produce or reproduce facial harmony.

To obtain the maximum in the artistic reproduction of the organs of mastication, the teeth should be placed upon the ridge as nearly as possible in the same position as the natural organs having roots which were fixed firmly in the gum tissue and their surrounding bony attachment. This effect cannot be accomplished in the majority of instances when a tooth of a flat character is used. But the difficulty may be overcome by selecting a tooth of ample size and good proportions in relation to the body of the tooth and the overlap at the cervix. Modifications can then be made to eliminate or produce certain lines which may be requisite and desirable to make harmony and confirmation in profile.

Evolution of the Human Face:

Chief Stages in Its Development from the Lowest Forms of Life to Man.

By WILLIAM K. GREGORY, Ph.D., New York, N. Y.,

ASSISTANT PROFESSOR OF VERTEBRATE PALEONTOLOGY, COLUMBIA UNIVERSITY; RESEARCH
ASSOCIATE, AMERICAN MUSEUM OF NATURAL HISTORY.

(Read before the Eastern Association of Graduates of the Angle School of Orthodontia. at its annual meeting, New York, May 8 and 9, 1917.)

I SUPPOSE if you have talked to people about evolution they have said: "Well, if monkey-like animals evolved into men at one time, why did not all monkeys evolve into men, and why are there any monkeys alive at the present time?" They ask me to explain it, and they regard it as an insurmountable objection to the theory that man has evolved from lower mammals. Now, I do not know why all the monkey-like animals did not evolve into men instead of changing only a little and remaining monkeys, but I do know that evolution, besides proceeding in different directions, also proceeds at different rates at different times. I know that just as there are many very advanced and progressive races, such as the horse and the humming-bird and the whale, which have undergone a very great modification during the vast period known as the age of Mammals, so there are also many conservative and backward races, such as the tapir and the opossum and the tuatara, which have undergone very little modification during the same period. These backward and primitive races are of the greatest use to us in deciphering the evolutionary history of past ages. They are living relics, or living fossils. A great many such relics are living today. That is what furnishes the material for comparative anatomy. It is by the dissection and study of these extant fossils and by comparing them one with the other, that we can trace out the stages by which structures have changed slowly one into the other, and by which

types have also changed one into the other.

—*Amer. Museum Journal.*

Young chimpanzee which has a short face and an exceedingly large forehead much like that of a young child (see skulls, page 124). (Photographed by Herbert Lang on the American Museum Expedition to the Belgian Congo.)

The monkeys and apes are relics of the middle periods of the age of Mam-

mals, and we know from the fossil remains that they have changed but little during that period. A possible reason is that most of them have continued to live in the forests and have therefore kept their primitive tree-living habits unchanged, while only a few, such as the baboons and the early predecessors of man, have left the forests and taken up wholly new habits on the plains, so that under the pressure of new conditions of life they have changed profoundly. But although other factors may be involved in the final answer to the question why all the monkeys have not evolved into men, it is true that by saving these relics of long past ages Nature has provided us with materials for elucidating the evolutionary history of human structures.

In considering the evolution of the human face, we gain a better perspective by beginning with the lowest animals and working upward. It seems that in the course of evolution the oldest part of the face is the mouth. The primary business of the face, in fact, is to direct the mouth toward the food. Some of the lowest, one-celled animals show this first essential of a face, which leads into a cavity that serves as a stomach, and among the anemones and corals and their relatives we find a well-developed mouth, surrounded by sensory organs (tentacles).

The flatworms show the presence of eyes in a very primitive condition—another structure which goes to make up the face of higher types; that is, there is a concentration of nervous tissue sensitive to light at one end of the animal, which is shaped so as to progress in a forward direction, with the beginnings of a head and of a tail. In *Peripatus*, a wormlike animal, there are little tubercles on the skin equipped with hooks which help to pull the food into the mouth, and a number of paired limb-like appendages on each side behind the mouth. These appendages become of importance in insects and crustaceans, those at the front end of the series becoming modified into sensory structures and also

in many cases serving to get food and convey it to the mouth.

In some insects the tough skin which covers these appendages has been modified into a sawlike edge, and here we have a suggestion of jaws, which are the next great element to be added to the face.

Finally, we see in many ordinary insects, such as a grasshopper, a rather high type of face for this grade of animal. It is completely armored on the surface with a tough skin. In many lower types of vertebrates also the head is armored like the rest of the body so that the head is protected by a helmet and the body by a cuirass. Insects naturally evolved a kind of face with a number of the characteristics of the face of higher animals, because some sort of face involving a mouth and jaws and paired sense organs is necessary at the front end of any animal that goes after its food in a fore-and-aft direction.

The very ancient fishlike vertebrates of the Silurian and Devonian ages also had a head covered with a bony skin which formed a cuirass and a helmet, and in some (*Bothriolepis*, etc.) the eyes were on top of this helmet much as they are in the grasshopper. The jaw parts of this vertebrate are likewise made up of bony plates on the surface, and no doubt the muscles pulled these jawlike plates back and forth much as they do in the insects. I do not mean that this fishlike animal with its grasshopper-like face has been evolved from the insect plan of organization; I am merely suggesting that general resemblances of this sort are frequently evolved in widely different groups in response to similar functional needs.

It is not until we reach the sharks, which are the most normal and typical of the fishlike vertebrates, that we see the vertebrate face in its typical form and that we see all the elements which are characteristic of the face of mammals. Even the familiar landmarks of the human face are all present. We have the nostrils, which are only indefinitely foreshadowed in earlier types;

we have the eyes, the mouth, the tongue, and the lips. But in the shark the whole face is covered with a tough skin.

In certain sharks (*Chlamydoselachus*) we see a suggestion as to how the teeth were formed in higher vertebrates. The tough skin, covering the head and body, is everywhere thickly studded with minute teeth, or denticles, the whole forming the shagreen of commerce. Now the teeth in the shark's mouth are nothing but enlarged shagreen denticles. At the

that the higher elements of the face, namely, the eyes and the nose, exist for the purpose of directing the locomotive apparatus toward the prey. In order to consume the food and transform its potential energy into action, the shark must of course have oxygen, which among fishes is extracted by the blood from the water surrounding the gills. These gills are supported by cartilaginous arches which are of the greatest importance in the later evolution of the

—*Amer. Museum Journal.*

In sharks we see for the first time the vertebrate face in typical form, with all the elements of the face of man—mouth, tongue, and lips to be brought into contact with the food by the locomotive organs, and nostrils and eyes to direct the locomotive organs. In the frilled shark (*Chlamydoselachus*) figured we see a suggestion of how teeth were formed in the higher vertebrates. The teeth within the shark's mouth are enlarged shagreen denticles such as grow on the skin outside the mouth. (After Garman.)

sides of the mouth the denticles gradually become larger and the skin that bears them becomes drawn over the margins and on to the inner side of the jaws. I need hardly say that the evolution of the teeth of vertebrates has had a great influence upon the evolution of the face.

In the shark the face is very distinctly the directing part of the animal, at the front end of the backbone. We may say that all the elaborate locomotive organs (the backbone, the fins, and the muscles which move them) exist chiefly for the purpose of bringing the mouth into contact with the food, and

face, since there is good evidence tending to show that the upper and lower halves of one of these gill arches actually gave rise to the upper and lower jaws of the sharks, which are equivalent to the cartilaginous core of the upper and lower jaws of all the vertebrates above the sharks.

The fishes called "ganoids," of many different varieties, show a shiny surface armature covering the face, as also the body, recalling the insects with their hard outer shell. But the noteworthy thing about this ganoid sort of face is that the hard covering of the face and

jaws has a bony substratum which completely invests the primary underlying brain-case and the primary or gill-arch jaws. This bony skin even extends inward along the roof of the mouth, forming the primitive hard palate, and along the inner as well as the outer side of the primary lower jaw, forming the sheathing bones of the jaw, which are typical of fishes and higher vertebrates. In this early stage of vertebrate evolution this bony mask lies fully on the inner and outer surfaces, but in the later evolutionary stages of all classes of vertebrates, these sheathing bones gradually sink below the surface in proportion as a new layer of skin is generated on *their* surfaces, and as this new surface layer becomes thicker the original sheathing bones finally come to be buried deeply under the skin and often tightly appressed to the still deeper primary brain-case and primary jaws.

There have come down to us from the age of Reptiles a great many fossil reptiles and amphibians which show this shell of bone still on the surface or very near the surface. Even in the modern alligators and crocodiles and turtles the bony mask lies immediately below the tough skin.

An aggressive-looking amphibian (*Cacops*) from the Permian of Texas has the general type of face which was destined to give rise by diverse modifications to the characteristic faces of reptiles, and indirectly to those of the higher types. It still has the mask of bone. It has a special interest, besides, since it possessed another very important structure in higher vertebrates—namely, an eardrum, which was doubtless stretched upon the bony rim behind the eye-sockets.

The Teju lizard represents a still higher grade of organization, the next step toward the mammals in one direction and toward the birds in another. It is an active, carnivorous animal, and its face is well protected by a mask of scaly skin. The bony mask is also still there, under the skin; but here is a point most important to remember, that if you took off the scaly skin of the face of this reptile, you would not find any facial

muscles beneath the skin, such as are present in our own face. It is only on the under side of the jaws and throat that you would find a layer of muscles beneath the skin. In the absence of true facial muscles all reptiles are inferior in rank to the mammals, where facial muscles first appear. Birds have the immobile non-muscular face of reptiles, further masked by a horny beak or bill; but the mammals have soft muscular lips and a muscular layer about the nose, eyes, forehead, and ears.

One of the greatest gaps in the whole record of the evolution of the face consists in this, that in spite of the relative abundance of living relics that preserve successive stages in the evolution of the skull itself, there is no animal known which has an intermediate type of face between the immobile non-muscular face of reptiles and the mobile muscular face of mammals. In spite of this, comparative anatomy furnishes fairly clear evidence as to the exact process by which the one did evolve into the other.

The facial muscles of a typical mammal, a lemur (*Propithecus*), for instance, correspond with the facial muscles of man. They include the platysma covering the throat, the orbicular muscle around the eye, the muscles of the nose, the muscles that lift the lip, the muscles that draw back the corners of the mouth, and the buccinator, which is of great use not only in blowing a trumpet, as its name suggests, but also in protruding the lips and pushing the food about inside the mouth.

All these various muscles of the face in man are innervated by branches of the seventh or facial nerve. The facial nerve comes out from behind the ear, and turns forward, one branch going to the platysma muscle on the surface of the throat and the other in numerous branches and sub-branches, like a vine and its divisions, passing forward to supply the muscles of the face. This fact gives the clue* to the origin of the

* Theory put forth by Ruge. This is generally accepted by anatomists as the true explanation of the origin of the facial muscles of mammals.

facial muscles. In the remote ancestors of the mammals only the platysma and the immediately underlying sphincter colli muscles were present; it is highly probable that this sheet of nerve tissue gradually spread from the under side of the throat upward and forward along the sides of the face, by degrees creeping over the old bony mask and beneath the skin, carrying with it the seventh

The facial muscles in man not only correspond with those in other mammals, but they also show special detailed resemblances when compared with the facial muscles of apes. Darwin and other investigators found that apes use these muscles much as we do, but with rather more emphasis than is usual in polite society. When a child first takes lessons on the piano, the teacher sometimes has

—*Amer. Museum Journal.*

All mammals have facial muscles, producing a more or less mobile face. These muscles are very highly developed in man. In a comparison of Gorilla (young) and white man (adult), homologous groups are seen such as the muscles surrounding the eyes, the nasal muscles, and the muscles that lift the lip. One of the greatest gaps in the evidence of the evolution of the face is that there has been found no intermediate type between the immobile non-muscular face of reptiles and the mobile muscular face of mammals. Comparative anatomy, however, shows how one may have evolved into the other. (After Ruge.)

nerve, and dividing and subdividing into numerous branches and layers; at the same time the nerve branched and branched again, as nerves have frequently been known to do when muscles became subdivided. Several analogous cases of the spread of a muscle layer into a new region are known or suspected, as in the case of the mammalian diaphragm, which is believed to have arisen in the neck region and to have migrated backward, dragging its nerves with it.

to remind him or her that the piano should be played with the hands and not with the face—and sometimes it takes considerable repression on the part of the beginner to keep the facial muscles still while striving to do anything with the hands that requires intense concentration and effort. A trained chimpanzee trying very hard to thread a needle has an intent expression and very tense lips, reminding us of the familiar human trait.

A gorilla in anger lifts the lips so as to expose the canine teeth and swells the muscles that run to the corners of the mouth so that they can be seen standing out on the side of the face. The arrangement of the wrinkles on the face in apes as well as in man seems to have a definite relation to the facial

The facial muscles are supplied by branches of the seventh or facial nerve, which issues from the skull behind and below the ear. It is believed that the throat muscle in remote ancestors of mammals spread upward between the bone and the skin, carrying the seventh nerve with it, and that as the muscle branched, the nerve also branched again and again, producing the highly mobile sensitive face of man. (From "Cunningham's Anatomy.")

muscles, often forming across the pull of the underlying muscles. Perhaps the principal difference between the facial muscles of man and those of apes, apart from differences in relative size, is that in man the upper lip is full and protruded while in the apes it is a thin "hard" lip, very muscular, but tightly drawn.

The human nose is hardly an inspiring subject from an anatomical point of view; internally it is decidedly de-

generate, as compared with that of other mammals, and externally it has nothing very wonderful about it, like the nose of the elephant or those of various bats. The adult human nose, at least in the higher races, differs from that of apes chiefly in the following characters: the bridge of the nose is higher; the whole nasal cartilage is produced forward and downward, often ending below in a well-shaped tip; the nose is narrower at the base in proportion to its height, and the nostrils face downward rather than forward. Now, however important these differences may be from an esthetic point of view, they are rather small from the standpoint of evolution, the more so since the nose of the human fetus in its earlier and less differentiated stages is decidedly more apelike than human. Even in babies the nose has by no means approached its adult human form. Among living apes the gorilla makes by far the nearest approach to the human condition in the shape of its nose, although the great width and the forward facing of the nostrils give it, according to human standards, a repulsive appearance.

In the face of the Australian black man we find some primitive gorilla-like characters along with others that are typically human. The nose is excessively wide at the base and the bridge between the eyes is very low, but the nostrils point downward and the tip of the nose is distinctly human.

A wonderfully well-studied restoration* of the extinct ape-man of Java (*Pithecanthropus*) shows a very wide nose, with the nostrils facing partly forward and partly downward, and with a deep depression above the nose, between the eyes; it also has a very thin upper lip and a partly everted lower lip; so that this mingling of human and apelike characters fully carries out the "missing link" idea which is so unmistakably indicated in the excessively low forehead and high brow ridges of this celebrated relic of a pre-human stage.

BRAIN-CASE AND FACE IN APE AND MAN.

—*Amer. Museum Journal.*

In the ape (young gorilla, at the left) the brain-case is comparatively low, and the face is shallow; in man (adult white man, at the right), the brain-case and the face are both very deep; the face has been retracted beneath the brain-case. (After Ruge.)

An interesting and grotesque caricature of certain human styles of nose is seen in two closely related genera of Asiatic monkeys, the "retroussé-nosed monkey" (*Rhinopithecus*) and the "proboscis monkey" (*Nasalis*). The former has the nose turned up at the tip and the nostrils facing forward, somewhat after the manner of a human fetus, while the male proboscis monkey, as its name indicates, has its nose produced into a long downwardly directed tube with the nostrils facing downward. In the mandrill the inflated nose is made more striking to the eye by the additional feature of intensely blue and red pigments.

It has long been suspected that these variations of the nose in the higher Primates, including man, may have been brought about through sexual selection, and that the form of nose has been determined by its decorative value, in accordance with the varied standards of beauty in the different races. Certain modern investigators, however, deny the potency of sexual selection to produce such results. Those who prefer to believe that differences in form are associated with differences in habit would perhaps favor the suggestion* that the downwardly pointing and hooded nostrils of man are primarily adapted to hunting habits and an upright gait, while the forwardly facing and open nostrils of the apes were adapted to frugivorous habits and a stooping gait. It may be also that the covered nostrils were better adapted for the rigorous, arid climate of the open plains, which according to my own view constituted the earliest habitat of men after they had abandoned their ancestral home in the forests.

Passing to a consideration of the origin of the human eyes, we find in the Primates many intergradations from the condition where the eyes are more lateral in position, to the anthropoid and human condition, in which the eyes are shifted together near the mid-line in front and can both be focused on an object near-by in front of the face. This process of

bringing the opposite eyes near each other has been carried even farther in the orang-utan than in man, so that the bony partition between the eyes in the orang is excessively narrow.

The eyes of all the anthropoids are very human in character, but especially those of the young gorilla. The back of the eye of the chimpanzee as viewed through an ophthalmoscope,* is extremely human in appearance, much more than that of the orang, so that this human character of the chimpanzee eye extends even to the arrangement of the bloodvessels and the appearance of the pigmented areas.

As everyone knows, the forehead of adult male apes is very low as compared with that of normal men; but the young, both of men and apes, have a swelling forehead. The baby orang-utan shows the domelike forehead of the human infant, and the young chimpanzee† has an exceedingly large forehead much like that of a young child. The inference has accordingly been drawn by some authors that the common ancestor of apes and men did not have a sharply retreating forehead but a domelike one and a relatively very large brain-case. Although space is lacking to discuss this question, I may be permitted to record my conviction that this inference is quite wrong, and that the human race has been derived from large, powerful apelike forms with heavy jaws, massive jaw muscles and a sharply retreating forehead.

The evolution of the human forehead is well suggested if we examine a series of skulls. In an adult chimpanzee skull the forehead is very low and there are heavy ridges over the eyes. In the skull of an Australian black man also the forehead is low and there are well-defined brow ridges. In a modern European skull the forehead is high and the brow ridges are lacking. In the shape of the forehead the extinct ape-man of Java

* According to the beautiful color plates of Dr. Lindsey Johnson. The gorilla is not figured among them.

† See illustration from photograph on page 115.

* Dr. George F. Stevens (*in litteris*).

was almost exactly intermediate between the chimpanzee and the lowest known human forehead, that of the Neanderthal race of the Old Stone age. The brain-case accordingly has progressively deepened in its vertical diameter as we pass upward from an apelike stage.

These changes in the contour of the brain-case merely reflect the more fundamental changes in the form of the brain, which in the higher types becomes excessively voluminous, and as it were presses out the forehead and skull top in all directions so that in short-headed races of men the head becomes almost spherical in form.

Every part of the bony face of Primates has no doubt been molded in the long run by the action of the facial muscles that press upon it. The partition of bone behind the eyes, for example, has grown downward and outward between the eye and its muscles which lie in front of it, and the powerful jaw muscle (temporal) lying behind it. The cheek bone has been deepened to give a strong support for the outer jaw muscle (masseter). The nasal bones have perhaps been molded to some extent by the muscles on each side of them.

In comparing men and apes one of the greatest differences is seen in the form of the front part of the upper jaw, which is associated with the marked differences in the form of the lips already alluded to, and with certain no less important differences in the character of the teeth and in the movement of the lower jaw. It seems very well established that as the primitive ape-men passed from the semi-erect to the fully erect posture, and as the rapidly expanding brain-case became balanced at the top of the progressively up-tilted backbone, the whole front part of the jaws and lips was drawn backward beneath the overgrowing front part of the brain-case; meanwhile the lower jaw and the whole head increased greatly in vertical height, but shortened equally in fore-and-aft length; the width across the brain-case increased, the sockets of the lower jaw moved apart, and the opposite halves of the jaws became sharply inclined toward

each other, so that the front teeth were all drawn backward; the palate and the lower jaw were thus shortened, and the dental arches assumed an archlike curve, the crowding of the front part of the jaw being partly associated with the marked reduction in size of the canine and premolar teeth.

A multitude of minor changes and readjustments took place at this critical time, but they were nearly all the direct result of the general tendency to shorten the face and draw it inward beneath the overgrowing, forward expansion of the brain-case. Among other important consequences of this general retreat of the face and its bony substructure were the downward and outward growth of the nose and the forward growth of the chin.

The evolution of the chin has given rise to an extensive literature. Some writers ascribe its existence to the excessive development of the genioglossus muscle, which runs from the hinder surface of the chin into the lower part of the tongue and which throws the tongue into the rapidly shifting positions assumed in articulate speech. Other writers ascribe the outgrowth of the bony chin to the withdrawal backward of the dental arch, to the increased pressure in the chin region, and to the turning outward of the lower rim of the jaw. Others regard the chin, like the nose, as a direct outgrowth, of no great functional importance, but linked in some way with the progressive improvement, according to human standards, in the appearance of the whole face. The present writer has sought to connect all these changes, including the reduction in size of the canines and bicuspid, with a profound change of food habits from the omnivorous-frugivorous habits of forest-living apes to the predatory carnivorous habits of plains-living men.

The profound disturbances and readjustments in the brain, brain-case, and face were accompanied by equally far-reaching changes in the backbone and in the pelvis and in the bones and muscles of the limbs. The forearms, no longer used in the stooping posture, shortened,

—*Amer. Museum Journal.*

SKULLS OF HUMAN INFANT (ABOVE) AND YOUNG CHIMPANZEE (BELOW).

The elements of the human skull are homologous with those of the ape, the differences between the two arising from the great expansion of the brain and the deepening and shortening of the face in man.

while the legs rapidly lengthened, so that men very early became fast runners on the open plains.

In conclusion, if we compare the skull of a young anthropoid ape with that of a young human being we shall find that every bone in the ape skull may readily be identified in a slightly different form in the human skull; the number and kinds of teeth are the same, both in the milk and permanent dentitions, and even the crown-patterns of the molar and bicuspid teeth are fundamentally similar in primitive apes and men. In spite of all the readjustments following the assumption of the fully upright gait and the change in food habits, the differences between the primitive ape skull and the

human skull are essentially differences of proportion and of degree rather than of kind.

From the paleontological viewpoint these numerous and fundamental resemblances can only mean that living apes and men have evolved from a remote and as yet undiscovered common ancestor that lived perhaps in the middle period of the age of Mammals. I believe also that the living apes, because they have stayed in the ancestral habitat, have retained the greater part of the ancestral man-ape characters, and that the ancestral pattern of the human face may still be seen in a little-changed state in the faces of young female gorillas and chimpanzees.

The Aims of the Subsection of Plastic and Oral Surgery.

By VILRAY P. BLAIR, Major M.R.C., U. S. A.,

IN CHARGE OF THE SUBSECTION OF PLASTIC AND ORAL SURGERY, SECTION OF SURGERY OF THE HEAD, OFFICE OF THE SURGEON-GENERAL OF THE ARMY, WASHINGTON, D. C.

(Presented before the Clinical Congress of Surgeons of North America, Chicago, Ill., October 24, 1917.)

OF not uncommon occurrence in the present war are those distressing wounds of the face and jaw which have attracted particular attention, not only on account of the disfigurement which they cause, but even more so from the difficulty that was at first encountered in dealing with them. This difficulty is the logical outcome of an attitude that regarded dentistry and surgery as two distinct and separate professions. As long as this theory was allowed to dominate practice, a man who had an extensive injury of the face and jaw-bone had about as much chance for an ideal result as had the man with an open fracture of a limb in the days when the physician and the bone-setter could find no common ground upon which to meet.

The bone-setter, and the physician who refused to recognize the surgeon, are of the past, but the surgeon and the dentist in their relation to each other only too frequently perpetuate the agnosticism of those older practitioners.

It is now accepted as axiomatic that in dealing with an open fracture of the thigh, the fixation of the bones and the treatment of exposed tissues should be concurrent, and that early treatment is one of the most important factors. It is not universally recognized that these same principles hold in the treatment of a wound involving the jaw-bone and the soft tissues, whether it be the result of an industrial accident, a removal of a tumor, or a war injury.

The surgeon has expended much study

upon making himself master of the various means of splinting an injured limb, but proper fixation of a fractured jaw can only be done by the use of dental splints. These he cannot apply himself, and he has not always sought the help that the dentist could so easily lend.

The late Von Langenbeck, after the war of 1870-71, said, "I would not care to go through another campaign without the help of skilled technicians to aid in the care of these jaw injuries."

The surgeon is not technically trained to splint these cases, yet early proper fixation is one of the most important points of the treatment. The dentist as such is not trained to care for the wounded tissues beyond fixation of the bones, yet repair of the soft tissues and proper drainage may be equally important. A few have bridged this no-man's land between surgery and dentistry, recently a much larger number have learned co-operation, but today I believe that the majority are pursuing their separate ways; that a patient with a jaw injury will be treated either by a surgeon or a dentist, neither of whom is master of all of the problems, and that either the fixation or the care of the tissues will suffer accordingly. Of the two, the dentist is the one more likely to recognize his need of help.

I crave pardon for injecting a personal note to the extent of begging that nothing be interpreted as the slightest criticism of the men who have been doing this work in the present war. We have a grave problem, and we must analyze the circumstances with which we have to deal. Anyone who is familiar with the results that have been obtained by Kazanjian, Hayes, Davenport, Mores-tin, Valadier, and the other men who have been doing this work abroad, can have but one opinion of what has been accomplished, but these men have now been engaged in this work for one or more years, while we have not yet started.

It is or has been the custom to transport these cases back to special centers where qualified men were stationed. In the meantime the patients receive what

might for want of a better term be called general treatment. We have recently been told by Crile that the most important step in the preparation for the care of our wounded is to plan to give them the proper operative treatment within the first twelve hours; that if this be done, primary union may be obtained in 90 per cent., and that gas gangrene, etc., may by this means be eliminated. This may be too much to expect literally of mouth injuries, but I feel absolutely certain that in over 90 per cent. of these cases earlier treatment would accomplish even better results than late treatment, where reconstruction must overshadow conservation, and that Kazanjian, Mores-tin, and the others, could accomplish even better results in the individual cases with less effort and less distress to the patient if they could have their plan of treatment started in the earlier hours after the injury, rather than later when the wound is complicated by infection, muscular spasm, infiltration of the tissue, or scar contraction.

In the light of our past clinical observation and of what we have learned from workers abroad, it is our hope to place in every evacuation base and recovery hospital men who are familiar with the problems and technique of dealing with these face and jaw injuries, so that from the very first each of these patients will receive the best that surgery has to offer.

Where are we to get the large number of trained men to do this work on the scale as planned?

There are in this country at present a large number of men who have specialized in oral surgery. These are men of dental training, many of them with medical degrees, who have gone beyond the treatment of the teeth, to devote their attention to the peridental structures. These men understand most of the oral problems, the application of splints, etc., but as a rule are not accustomed to doing the major surgery that is required for many war injuries.

The surgical principles of treating oral and face injuries are the same as those applicable to wounds of any part of the

body. Wounds of the soft parts, if seen early before infection has occurred, may frequently be immediately repaired by suture. The wound is cleaned of all blood-clots, hemorrhage is controlled, and foreign bodies are removed; with the latter are included totally detached bone fragments. Above the lower border of the body of the mandible, local and general conditions permitting, immediate closure of the wound should be made, but all shreddy and pulped tissue is removed by clean excision, no attached fragments of bone being removed. If the defect is too large for simple suture, then, local and general conditions permitting, undermining of the borders may be done with provision for drainage of these pockets, or the wound is closed by flap operation. If the parotid duct is severed, provision for drainage into the mouth is made. In the neck there are two particularly notable danger zones in reference to subsequent infection: (1) The lower parts of the sub-facial spaces that lead directly into the mediastina, and (2) the immediate wound area about the ligated carotid or carotid primary branches. In the first instance the danger is that of mediastinitis, whereas in the second it is the possibility of secondary fatal hemorrhage. The blood supply, and therefore the resistance to sepsis, is not so good in the neck, and drainage may be necessary. If the deep sub-facial spaces are opened, in the deepest part of the lower end of each invaded space a small strip of gauze packing is placed. If one of the primary branches of the external carotid artery is divided, this part of the wound is packed, because sepsis here predisposes to fatal secondary hemorrhage. A wound in the trachea or larynx may be sutured, the more superficial part being packed, to furnish drainage away from the tracheal lumen. A wound of the pharynx or esophagus is sutured, and the line of union reinforced by some superimposed tissue, but the mediastinum is guarded by a light packing at the lowest part of the wound.

These packs are not allowed to remain when fouled. A complete wound through the floor of the mouth, as Billroth long ago pointed out, should never be primarily sutured, on account of the danger of indurating infection and secondary hemorrhage. If the bones are involved, then the remaining portions should be splinted in their proper positions and no attached fragment removed. Every pocket, every open bone-cavity, and the lower end of every fracture line should have efficient dependent drainage. If this be done early, it is surprising to note the conservation and regeneration that may result. After the bony fixation and drainage have been provided for, then the soft parts may be repaired as outlined above. The necessity for late repairs will largely be in inverse ratio to the early care that the case has received.

It is by associating the capable general surgeon with the dental oral surgeon and sending them out as units that we propose to furnish this skill in multiple. If any apology were needed for this plan it is to be found in the recent report in a lay journal by Dr. W. W. Keen of the operation performed upon the late President Cleveland, in which one maxilla was removed and replaced by a prosthesis so perfect as to defy detection. This was an example of co-operation of the surgeon and the dentist.

In order to correlate the work and to present the special war problems, short-course schools have been established by the Surgeon-general in several cities where these surgeons and the dental oral surgeons working together will be molded into working units. Until their services are needed abroad these units are co-operating with the dental surgeons in the cantonments in an attempt to eradicate peridental infections from the mouths of our soldiers. It is hoped by this to materially lessen the medical casualties on the other side.

These are the aims of the subsection of Plastic and Oral Surgery in the program of "preparedness."

Dental Bibliography: The Need of an Index of Periodical Literature.

By L. PIERCE ANTHONY, D.D.S., Philadelphia, Pa.

AS soon as there had been published a sufficient amount of literature pertaining to dental subjects to constitute what might be termed a literature of dentistry as a special branch of the healing art, those interested in the literature of this specialty began to make definite efforts toward the compilation of bibliographical records of dental literature.

As early as 1793 there was published in Leipzig in *Neues Magazin für Aerzte* a list of the dental works that had been published up to that time. The next effort appeared in 1829, as an appendix to Fitch's "System of Dental Surgery," published in New York, and constituted a fairly complete list of dental books published in the United States. Following that and previous to 1851 several other lists of dental books were published, notably those by Maury, of France; Linderer and Carabelli, of Germany, and Goddard, of the United States. In 1851 there was published by Robert Arthur, in the *American Journal of Dental Science*, as a "Report on American Dental Literature" to the American Academy of Dental Science, a fairly comprehensive list of dental works published in America previous to that year.

There was then a lapse of some fifteen years before any other dental bibliographer attempted to make a record of the dental literature. In 1876 Dexter published his "History of Dental and Oral Science in America," and in this was included a list of dental publications, which was, however, very incomplete; his effort being more in the nature of a review of the most important dental works published in English, together with a

record of the periodicals then published, with no particular effort at giving a complete record of the periodical literature.

In 1885 there appeared the most conspicuous effort at dental bibliography yet undertaken in America, in the publication of Crowley's "Dental Bibliography," a remarkably accurate record of the dental literature of the world, covering the period from 1536 to 1885. This today is a classic in American dental bibliographical work, and is the most authentic record we have of dental literature up to and including the year 1885.

The next most notable effort in dental bibliography was that in 1891 by Sternfeld, who published a work of excellent value, and one which ranks with Crowley's as a remarkably faithful record of the dental literature which had appeared up to and including the year of its publication.

In 1886 Taft's "Index of Dental Literature" was published, and was a fairly complete record of the periodical literature of the United States up to that time, and compiled almost entirely from the literature that was familiar to the author in his career as student, practitioner, teacher, and editor.

It was, however, left for Port, a German bibliographer, to publish the most elaborate record of periodical dental literature yet attempted. Port's work began in 1910, and the first volume included the literature, both books and periodicals, from the beginning of dental literature until 1902. This index was published in separate volumes for each year up to 1907, but we understand that further effort in the direction of bringing this bibliography up to date has been

suspended on account of the war conditions at present existing.

The two most notable efforts at the publication of monthly indexes including both book and periodical literature are those by Lamb, published in the *DENTAL COSMOS* from March 1889 to December 1902, and Paul de Terra, published in *Archiv für Zahnheilkunde* for the years 1911, 1912, and 1913.

Lamb's index was a fairly complete monthly record of book and periodical literature of the time. Paul de Terra's work, however, was more elaborate, and was a remarkably complete record of the monthly literature of the world, including the literature of almost all languages and countries of the world.

David, a French bibliographer, published in 1889 a very accurate bibliographical record of French literature, but did not include in this any dental works published in other languages.

The most recent dental bibliographical record in America comes from the Surgeon-general's office in Washington, and is a splendid historical record of the dental books and periodicals published in all countries, but is unfortunately incomplete in that it only records the publications that are on file in the Surgeon-general's Library.

In the foregoing the writer has only attempted to give a brief history of the efforts at dental bibliography in the past as a matter of historical interest and record.

We shall devote the remainder of this article to an attempt to impress upon the reader the necessity for renewed activity in the bibliographical field, and cite some of the many apparent reasons why such records of our literature are more necessary and important today than ever in the history of our profession, in an endeavor to stimulate a more lively interest in this subject than has been exhibited in recent years by those most vitally interested in the educational development of dentistry.

The literature of a profession is the permanent historical record of its progress and advancement, and every member of that profession should be sufficiently

interested in his own advancement and progress to keep abreast of the progress made by his professional *confrères*. There is only one way in which the dentist can keep in touch with the advancement of his profession, and that is by constant reading of the periodical literature in which is recorded from month to month the latest improvements and suggestions in the various methods of dental procedure. As a previous writer on this subject aptly expressed it, "The periodical literature of dentistry is a serial story, an ever-unfolding record of dental achievement. Each instalment, whether it be a copy of a journal, a book, a pamphlet, or a report, adds its 'incidents' to the main trend of the story."

The dental profession has long borne the stigma of being a non-reading profession, and we regret to have to admit that in the past there has been a certain degree of justification for such a charge, but with the ever-increasing responsibilities to humanity that are devolving upon the profession because of the widening of the scope of dentistry, it is coming to be clearly recognized that we can ill afford to allow such a stigma to continue to rest upon the profession.

Dentistry has developed with such giant strides in recent years that it has become necessary for a division of the profession into numerous sub-specialties until today we have as specialties of dentistry orthodontia, prosthodontia, exodontia, periodontia, radiodontia, oral surgery, and even further specialization in particular operative procedures.

Coincident with this broadening development of dentistry has been the development of the literature pertaining to each of the specialties, and consequently an increasing necessity for the specialist to keep abreast of the advancement in his own specialty as well as to keep himself familiar with the advancement of other specialties in their relationship to his own. In addition to this we have devolving upon dentistry larger responsibilities that have been forced upon it by the important rôles that oral sepsis and oral infections play in general systemic disturbances.

The claim has been made with some justification that the reason why dentists do not read more is that they are too busy in their practice and are too tired and mentally exhausted when their day's work is done to devote any considerable amount of time and energy to study, but in this respect we have the peculiarly anomalous condition that the busier the dentist the more important and necessary it is that he should study and read for his own benefit in the way of learning improved and possibly shorter methods as well as for the benefit of the larger percentage of the community that he serves.

The literature of the profession and its specialties has become so extensive that few busy dentists can afford the time to wade through the mass of matter published monthly to sift out that which is most important to the special reader. It is for this reason that we believe the time has arrived for a definite and permanent effort to be made to publish a monthly index of dental literature that will serve as an intelligent directive guide to the busy dental practitioner with limited time available for study.

Recognizing the need for such an index, the National Institute of Dental Teachers some years ago inaugurated a movement which resulted in the establishment of the Dental Index Bureau to devise ways and means of publishing a monthly index of dental periodical literature. The Bureau proposed to publish a monthly index of, say, six journals on the Dewey decimal system of index classification as adapted to dentistry by Dr. Arthur D. Black, but thus far there have been no material developments from the project.

The Dewey index system is undoubtedly the most comprehensive system of indexing in existence today, but the writer believes that it is too elaborate for practical application to the purpose indicated. We are of the opinion that a classified subject index after the plan adopted by De Terra, or the *American Medical Association Journal's* "Quarterly Cumulative Index of Medical Literature"

would be of as much value, and possibly more, to dental readers generally than an index based on the Dewey system, and would certainly involve less labor and expense in its production.

It is not practicable or even desirable that every dentist subscribe for and read every dental journal published, but with the aid of a monthly index he could read special articles in many journals, and if he desires to read more extensively on any given subject there are today very complete dental libraries in nearly every section of the country that are accessible to dentists of the various sections.

Within the past few years—and this I may cite as concrete evidence of an awakening on the part of the profession to the importance and value of a familiarity with the existing dental literature—there have been established complete and comprehensive dental libraries at Harvard Dental School, Boston; Northwestern University Dental School, Chicago; University of Pittsburgh Dental Department; University of Pennsylvania School of Dentistry, Philadelphia; Washington University Dental School, St. Louis; Columbus Dental Society, Columbus, Ohio; the DENTAL COSMOS, Philadelphia; Academy of Medicine, New York; the Surgeon-general's Library, Washington, D. C.; Eighth District Dental Society of New York, Buffalo; the Dental Departments of the University of Michigan, Ann Arbor; University of Minnesota, Minneapolis; the University of California, San Francisco, and the University of Southern California, Los Angeles; as well as a few notable private collections. Each of these libraries, of course, is cataloged for library purposes, but for the investigator who wishes to search the literature of a particular subject the lack of any index covering the literature of that subject is an obstacle to such research that can only be overcome by diligent and necessarily indiscriminate search which consumes an amount of time that few busy dentists can afford to expend on purely literary effort. So that the value of such libraries as have just been mentioned can

only be fully realized when a subject index that will be as an "open sesame" to the valuable store of knowledge contained therein is available to all who wish to take advantage of these collections.

The writer has been associated in the collection of what he believes to be one of the most comprehensive collections of periodical dental literature in the English tongue, which has for years been accessible to all dentists in the vicinity of Philadelphia for reference reading, but very few have availed themselves of the advantages of this "mine of dental wealth untold," mainly for the reason, we believe, that it has appeared to the dental researcher as an undertaking too staggering in its immensity to attempt to search through the literature of a particular subject without the aid of an effective and practical index to guide him.

The DENTAL COSMOS Library is constantly receiving communications from dentists asking for references to a given subject, and while we are always glad to assist the applicant as much as possible, such an index as we have suggested would meet the needs of the inquirer certainly much better than could individual answers. We further believe

that facilitating reference in some such manner as herein outlined would give an added impetus to more general reading on the part of the profession, and would, we hope, remove from dentistry the stigma of being a non-reading profession which it has so long borne.

A Case of Nasal and Palatal Restoration.

By GEORGE G. BELL, D.D.S., Ashland, Ky.

THE patient, Miss G—, having an acquired cleft palate and loss of nose, was sent to me by a charitable institution. A cast of the face was made after inserting a tube in the opening left by the lack of nose tissue, with soft plaster poured over the entire face, which was previously greased with cocoa butter. A matrix of stiff cardboard, passing under the chin and forward of the ears, was

used in making the cast, the assistant holding the cardboard matrix while the plaster was being poured. A model was then run, and a nose was made from pink wax and tried on the patient. A compound impression was taken of the mouth, and from this impression a model was made of wax, chilled, and placed in the mouth. A Gilmore attachment was used in the obturator and the wire left in

place when it was vulcanized. This wire was later removed, and in fitting the nose

small hook was placed at the upper part of the nose to engage a pair of glasses

FIG. 1.

FIG. 2.

FIG. 3.

a new wire was placed in the attachment on the obturator and allowed to pass into the nose. When the nose was vulcanized, the wire was vulcanized in it. A

that held the nasal restoration in place. The accompanying illustrations show the case before and after treatment, and the finished artificial restoration.

An Experimental and Clinical Study of the Isolated Thyroid Hormone.

By NELSON W. JANNEY, M.D., Ph.D., New York, N. Y.,
ASSISTANT PROFESSOR OF MEDICINE, NEW YORK POSTGRADUATE MEDICAL SCHOOL
AND HOSPITAL.

Address delivered before the annual meeting of the Eastern Association of Graduates of the Angle School of Orthodontia, New York, N. Y., May 7, 1917.

MR. PRESIDENT, LADIES AND GENTLEMEN:

I FEEL in coming to you from another field of research, in which I have spent years of my life, that we have much in common. Let us look at these studies as brothers in endeavor should.

In presenting the work this evening I have thought that it would seem a little one-sided if I confined my talk entirely to a report of our investigations on the thyroid gland and its hormone. It would make it somewhat broader to speak a little more generally about the ductless glands, and perhaps of some new viewpoints in regard to the function of these organs.

When we come into the realm of hormone therapy we have at once one of the most fascinating sides of medicine, but unfortunately one of the most confusing, presenting perhaps more difficulties than any other in this field of work. The causes for this are quite obvious, but I might take merely a minute to recall them to your mind. The ductless glands are often very unfavorably situated anatomically, as you know, and therefore can become available to research only after overcoming great obstacles. Take, for example, the pituitary, which is situated at the base of the cranium. Aside from the location, I may allude to an added difficulty in the fact that, with very few exceptions, these hormones are not stored in the ductless glands, but are constantly given out into

the circulation. Again, certain endocrine glands, such as the parathyroids, bodies necessary for life, are very small. I removed some recently from a dog, and the entire amount did not weigh more than one-tenth of a gram.

The amount of hormone in these ductless glands is also extremely small. I have made calculations recently which indicated that there are no more than about 40 mgm. of the hormone present at any one time in the thyroid. The chemical difficulties presented in isolating this very small amount of substance are enormous. When we consider the parathyroid glands, and think how minute is the amount of hormone excreted by them, we can realize some of the obstacles which must be overcome in solving these problems.

The solution of this whole hormone question lies in chemistry. We shall never be able to make advances in hormone therapy without increased knowledge of the chemistry of the hormones.

Before we begin a consideration of our own studies, I should like to call attention to two other points, namely, the changes in the nature of the hormones during preparation; and the question of dosage of endocrine preparations. In these days, when the medical practitioners are administering all kinds of glandular extracts, we ought to appreciate the uncertainties attending this treatment as carried on at the present time. The great difficulty in obtaining

an extract which promises to represent the active principle of the gland lies in the fact that we know little about the chemical attributes of the hormones. Certain it is, however, that changes in their chemical constitution, therefore very probably in their effect on the organism, may result from the mode of their commercial preparation. As to the dosage, I may mention that in our own studies we have found that one may get two entirely opposite effects on the organism, according to the amount of thyroid gland or its preparations administered.

We know that thyroid extract administered from without is a substitute for the thyroid secretion in the cases of cretins who are without thyroids or who have diseased thyroids, but we have never until recently had in our possession the isolated thyroid hormone. Various preparations have been made from the thyroid for the past twenty-five years, and various physiological experiments carried out with them, but none have demonstrated that the actual hormone of the thyroid had been obtained.

ISOLATION OF THE THYROID HORMONE.

About 1914 Dr. E. C. Kendall of the Mayo clinic began experiments with the aim of isolating the thyroid hormone. The difficulties to be overcome were tremendous, as I stated before. Dr. Kendall has told me that he has worked up chemically about a ton of thyroid tissue to obtain five grams of approximately pure thyroid hormone. He has of late practically devoted all of his time to this problem, and I have every reason to believe that he has been generally successful. He has isolated a crystalline body from the thyroid gland which certainly presents more definite characteristics than anything yet obtained. The empirical formula of this substance is $C_{11}H_{16}O_3NI_3$, and it may be designated from its structural formula, according to Dr. Kendall's views, as tri-iodo-trihydro-oxy-indol-propionic acid. This chemical body, when pure, consists of microscopic

sheaths of white crystals which are very refractive, so that quite a beautiful sheen is visible in the test tube when they are floating in it. It contains about 66 per cent. of iodine in the pure condition. The iodine contained in this represents about 50 per cent. of the total iodine of the thyroid gland. The hormone is quite soluble in water: it has a constant melting-point, and is undoubtedly a fixed chemical compound.

TOXIC ACTION OF THE THYROID HORMONE.

It now becomes necessary to prove whether or not this substance possesses the physiological characteristics which have been ascribed to the thyroid, for, after all, the physiologic and therapeutic tests are the most important.

Through Dr. Kendall's generosity I secured possession of a few hundredths of a gram of the hormone, which has been sufficient to carry on our work for over a year. Investigations at the Mayo clinic had shown that this hormone preparation had undoubtedly a therapeutic effect in myxedema and cretinism, and also produced toxic symptoms in overdose. These results were brought about by metabolic changes which urgently required investigation. Accordingly, the facilities for such studies offered by the Montefiore Hospital of this city were utilized, and metabolic studies were carried out by us in the laboratories, the animal experimentation rooms, and the metabolic ward of that institution.

Inasmuch as it was an entirely new remedy, I felt that perhaps the proper thing to do would be to begin right at the beginning, and test it as if no work had been done at all. We first took a dog and injected quite a large amount of this hormone solution subcutaneously. He showed for the first twenty-four hours practically no change, then began to develop marked symptoms of hyperthyroidism. He showed a high fever, great nervousness, very fine tremor, characteristic of Graves' disease, also great sensitiveness to touch: excepting

for the condition of the eyes, he exhibited practically all the symptoms of Graves' disease. A large dose of thyroid tablets would give precisely this clinical picture, therefore we knew that we were dealing with an active thyroid preparation. I shall show you later a slide demonstrating the effect of these thyroid injections on the dog's metabolism. As you will see, a veritable metabolic storm was the result.

Anyone who has followed clinical work knows how easy it is to be deceived by changes in the clinical picture of a case. We try one remedy after another and if the patient improves, we are tempted to come to the conclusion and write a paper showing that the patient recovered only because he followed our treatment. However, the patient *might* have gotten well without the drug. I felt that we must have a more accurate gage than merely following the clinical picture in this study. This brings us to a consideration of the effect produced on the metabolism by the thyroid gland, because a study of this effect afforded us a more accurate means of following the general changes in the patient's condition, as the chemical processes are fundamental and can be more exactly followed than clinical symptoms.

THE NITROGEN BALANCE AS A GAGE OF THE EFFECT OF THYROID PREPARATIONS.

We have long known that the thyroid acts as a stimulus to metabolic processes. In the treatment of obesity, large doses of thyroid will cause people to lose weight, such loss being accompanied by a considerable loss of nitrogen to the body. The action of the thyroid on metabolism has therefore been regarded as a stimulus to protein breakdown, or catabolism, with a consequent loss of nitrogen. This view has always seemed to me paradoxical, for the reason that we know that growth is controlled a great deal more by the thyroid than was formerly supposed, this gland having almost as much control of growth as the pituitary. Nitrogen must be gained and

not lost by the growing individual, because growth entails the building up of protoplasm, and that in turn means the putting on of nitrogen. Therefore if the thyroid functionates to promote and encourage growth, its physiological action must cause retention of nitrogen. In clinical medicine, however, it has been held that when we give a patient thyroid we stimulate catabolism, and nitrogen is lost. Where, then, do we stand?

In the last year or so, through the work of Schaeffer and Hewitt in England, some extremely interesting new data were obtained. They found that if thyroid in relatively large amounts was fed to white mice no growth took place, and nitrogen was lost; but by reducing the amount of thyroid these workers finally reached a dosage which *stimulated* the growth of the animals. Nitrogen was retained in increased amounts under these circumstances. In this latter case we evidently have a true physiologic action—the *anabolic* effect of the thyroid in contradistinction to the catabolic action which was hitherto considered the only function of the thyroid.

Therefore this work really pointed out the path. We thought perhaps by studying such a mode of procedure we might find a more accurate way of measuring the effect of the thyroid in general by a study of the nitrogen metabolism. These experimental findings were accordingly applied to the human individual, and without going into any more detail than necessary, I might say that we have pretty definitely been able to prove that *when the thyroid exerts a physiologic or therapeutic effect on the organism, and not a pathologic or toxic effect, we find that nitrogen is retained in the body in increased amounts.* This finding afforded us a way of more accurately following the effect of the hormone treatment than had been heretofore possible. A metabolism ward was developed in the Montefiore Hospital with the idea of using this gage of the effect of thyroid medication. The patients were isolated in this ward, and were put on weighed diets containing known amounts of nitrogen. The excretions were exam-

ined for nitrogen, and a daily balance of the nitrogen intake and output established over long periods; then by noting how these patients were reacting, and by administering thyroid, we were able to follow with considerable accuracy its real effect on the metabolism. This was the method employed throughout our work.

EFFECT OF THE THYROID HORMONE IN THE NITROGEN BALANCE.

We then began a series of studies with the thyroid hormone. The first experiment I have already mentioned—the effect of an overdose on the dog's metabolism. Then another series of experiments was undertaken. Patients were put on the fixed diets, and the nitrogen balance determined. I might say that this balance is merely the nitrogen which goes into the body and the nitrogen which is given out by the body, subtracted one from the other; that is, if the nitrogen which is lost is greater than the nitrogen which goes into the body, the balance is negative, and *vice versa*. It may become more or less positive or negative as a result of the thyroid medication. As you will see by following the lantern slides, a good method of control had thus been established. Whenever we found that the therapeutic effect was in evidence, an increase in the positive balance was observed.

We soon found that extremely small amounts were enough to influence metabolism, and metabolism was affected (this is the point) *before the appearance of clinical symptoms*. We were never forced to give enough to produce clinical toxicity, because we could tell by our nitrogen examinations how far we dared go. We found that a very minute amount of thyroid did influence the organism. How small an amount was effective you may judge from the fact that in one or two cases a few hundredths of a milligram of hormone influenced metabolism considerably, and caused an amount of weight and nitrogen to be lost that was quite appreciable.

This effect was determined in a series of normal control subjects. I might say

that these experiments required to be carried on over long periods of time. One day's nitrogen balance means very little; a week's balance means a little more, but to draw definite conclusions the balance must be followed for a long time. We tried to live up to this ideal, paying no attention to daily figures, taking the mean of all the weekly balances, and using the mean figures for comparison. Our cases were examined in this way over periods varying from three to thirty-seven weeks.

EFFECT OF THE HORMONE ON PATHOLOGIC CONDITIONS.

Graves' disease. Having completed the preliminary series of controls we felt privileged to go farther and study pathologic conditions. First we studied a series of exophthalmic goiter or Graves' disease patients. This condition has been explained for decades as one of hyper-function of the thyroid. There is an excess of thyroid metabolism. If this were true, thyroid medication would not be expected to benefit those suffering from this disease. Indeed, it should have just the opposite effect. There are, however, many objections to be made to the hyperthyroid theory of exophthalmic goiter which I cannot go into now. We felt it therefore proper to determine the effect of the thyroid hormone in Graves' disease with the aid of metabolic studies, in the hope of answering the question finally, "Does thyroid therapy avail anything in this condition?"

We subjected a number of such cases to this metabolic control—i.e. adding varying doses of hormone as sole medication to the carefully weighed diets, analyses being made daily. We feel that we have quite definitely determined through this work that the thyroid hormone does not benefit exophthalmic goiter. There were, indeed, some cases which showed an appreciable gain in nitrogen retention and weight, and a betterment of the clinical symptoms, but in two-thirds of the cases this did not occur. Therefore we were forced to dis-

miss the possibility of exophthalmic goiter coming under the therapeutic range of this new remedy.

Cretinism. The most interesting results yet obtained have been in the hypothyroid conditions. A case that has been under observation was one which seemed absolutely hopeless as regards treatment. A young woman of twenty-three had the mental development of a child of six, and presented all the well-known marks of cretinism. This case had been treated previously with thyroid tablets, and had been declared by an internist not to be a case of cretinism because it did not respond to thyroid treatment. As a matter of fact, this cretin then was receiving a toxic dose, and there was at that time no way of measuring its effect. From the clinical symptoms it was evident, however, that the catabolic effect was being obtained, and this cretin was losing ground, not gaining, on the very therapeutic remedy which was her only salvation. In our own experiments we felt that we should give our metabolic theory a pretty rigid control, so we did not confine ourselves to giving thyroid hormone, but also fed fresh thyroid gland. We observed that the nitrogen balance was very markedly increased when the fresh gland in proper doses was administered. Only after we had carefully studied her metabolism did we prescribe any thyroid medication. Having gained a definite idea as to her metabolism we could determine with considerable accuracy how large a thyroid dose she should have.

We found that we were dealing with much more delicate changes and dosage than had been supposed to exist in the past. As you know, the usual medical dose of compressed thyroid tablets is about five grains three times a day. We found that when we gave our patient an amount of thyroid hormone which represented half a milligram of iodine once a day, we were giving her too much; so much so that she showed toxic symptoms. First there would be a peculiar dropping off of the plus nitrogen balance. This was always the first sign to appear. Other symptoms did not develop for a week or two, then there en-

sued a slight attack of tachycardia and precordial distress.

As you have noted, we measure the amount of hormone in terms of the hormone iodine, which represents by weight about two-thirds of the amount of hormone present.

Then we gave our patient an amount of hormone equivalent to one-tenth of a milligram of hormone iodine. She still failed to gain. By persistence—and the labor was rather severe, as it took a great deal of laboratory work and several men's time—we found the optimal dose for this cretin to be *one-fourth of a milligram of hormone iodine daily*. This dosage as worked out could be corroborated from other clinical observations, and we found that this is about the right dose to make a cretin grow. On this dose our cretin now gained; she felt better and the nitrogen balance increased. We had now a clear explanation of her previous difficulties in the general medical wards, where she was receiving five grains of the dry extract three times a day. Upon reckoning this amount in terms of the hormone, it was determined that she was at that time receiving something like 125 per cent. more thyroid than she should have been getting, and that therefore toxic symptoms were showing themselves as I have described.

THEORIES CONCERNING THE PATHOGENESIS OF GRAVES' DISEASE.

I may now refer to a certain hypothesis which I have ventured to mention once or twice before in private as regards the possible origin of exophthalmic goiter. As is well known, exophthalmic goiter is characterized by a very strong outbreak of toxic symptoms, and the nitrogen breakdown is probably due to this toxic effect upon the protein tissues. The following is a possible chemical explanation of this toxic outbreak. We see here on the blackboard the formula for the normally occurring amino-acid histidine, terminating in the acid group, COOH . It is well known that when histidine undergoes a certain breakdown this group is broken

off, leaving what is known as B-aminazolethylamine. Histidine, unless taken in relatively large quantities, is not toxic, but this substance which is so intimately related to it is very poisonous. A minute quantity is capable of killing a guinea-pig. The point which I am trying to illustrate is that a compound normal to the body can become extremely toxic by undergoing but a relatively moderate change in its chemical constitution. I have applied this same explanation to the question of the thyroid. The thyroid hormone possesses an acid group, COOH. Were this to be split off a toxic body might be formed. The symptoms of exophthalmic goiter might be due to the circulation of a highly toxic, improperly synthesized thyroid hormone.

I shall close with a short consideration of the action of hormones in general, and of the theories that have been advanced to explain that action.

THE SPEAKER'S HYPOTHESIS OF ENDOCRINE FUNCTION.

The action of the hormones on the organism is an exceedingly intricate question. I have represented here on the blackboard in a brief, graphic way the celebrated theory advanced by Falta, Eppinger, and Rudinger, and advocated by many of the Viennese school, including Von Noorden, regarding an explanation of the interaction of the chief hormones. They believe that aside from an action which each hormone has for itself, it also has an action on other of the endocrine glands; for instance, that the thyroid exercises a depressing effect on the pancreas and a stimulating effect on the suprarenals, and that the suprarenal bodies exert a depressing effect on the pancreas, etc. They were thus enabled to account for a great many clinical observations.

Thus it has been observed in Addison's disease that the patient can ingest large quantities of sugar without a sign of sugar in the urine. This is explained by the Viennese school by the fact that the suprarenals exert a depressing effect on the pancreas normally, and when this influence is removed, there is nothing to prevent the pancreas from overact-

ing. More sugar could consequently be burned up, and the tolerance therefore would rise, and the patient would be able to eat more sugar without having it appear in the urine.

This theory is so exceedingly elastic that almost anything can be explained by it. It is also exceedingly complex, although I have tried to present it as simply as possible in the example that I have given you.

Recently we have done a little work to test this theory experimentally. We attacked this problem from another viewpoint by a chemical investigation of the blood sugar. In a series of experiments on six or seven animals, we made the very interesting observation that when the thyroid was removed from these animals there was a large decrease in the blood-sugar values. The decrease ranged from 25 to 30 per cent. This finding apparently bore out the theory of Falta, Eppinger, and Rudinger. We suppose that the blood glucose was thus decreased because, the thyroid being removed, the pancreas was over-stimulated and that more sugar was burned. However, we determined that this was not the true explanation.

We had previously studied the blood-sugar curves of normal animals—*i.e.* the length of time that it took for the blood sugar to return to its normal value after the ingestion of a definite amount of sugar. We found that the normal level was reached in two hours after the carbohydrate was administered. On repeating these experiments after thyroidectomy, we found that it took four or five hours' time to return to normal. This was remarkable because, if the Viennese hypothesis was correct, the sugar should disappear out of the blood more quickly due to the over-stimulated pancreas, and the blood-sugar curve should be consequently shortened.

We thus observed actually a decreased ability to remove sugar from the blood after thyroidectomy. This makes it clear that we are dealing with a new phenomenon. We had discovered the reason why the tolerance for carbohydrates was apparently increased after thyroidectomy. It was not because the

pancreas could split more sugar, but because the blood-sugar level was low, and owing to this fact, though the carbohydrates could not be readily removed from the circulation, the sugar concentration never rose high enough to cause a urinary excretion of sugar. The theory of Falta, Eppinger, and Rudinger in explanation of the action of these glands is thus experimentally confuted.

If we collect data bearing on the action of the endocrine glands and the effect on the organism when certain of these glands are diseased or removed, we must come to the conclusion that many of these organs have similar functions.

In diseases of certain ductless glands it is pretty generally recognized that there exists a disturbance of other of the glands. If the pituitary is affected the thyroid is liable to be, and the suprarenals, and so on. It is certain that there is a synergistic action between the various ductless glands, and that perhaps their action on the organism, which is nothing more than the effect on protoplasm, can be represented graphically, not by the triangle of Falta, Eppinger, and Rudinger, with arrows running in both directions, but by some such scheme as an octagon in which the thyroid, the

ideas which I have put together regarding what seems the most logical hypothesis of endocrine action capable of being devised at present. To exemplify: If the thyroid is removed, growth does not stop entirely, the organism being able to carry out these processes to a certain extent, the thymus frequently increasing in size. Therefore in the building up of the protein molecule various glands apparently exercise similar functions.

As to how the functions are carried out we are still in the dark, but the question is being chemically studied. I am inclined to believe that it is a matter of the synthesis of the protein molecule by the action of various hormones on its component parts, the amino-acids.

Let us suppose a given amino-acid like lysin, containing six carbon atoms, is to be built up in the body of various simpler groups. It is known that substances supplied by the food usually contain not more than three carbon atoms. Let us suppose that the function of the pituitary is to link together the three carbon atom compounds into this particular amino-acid. Perhaps the thyroid has to do with the linking of lysin with other amino-acids to build a polypeptid. Another hormone may be necessary to unite various polypeptids into protein. Under normal conditions each gland has its own division of this work, but may under stress take over some of the work of others.

However, do not take this theorizing too seriously. It is at present an absolutely unproved hypothesis. There is no proved theory of the action of the ductless glands: there are a few hypotheses, and this is merely a new one. The one which has heretofore been more or less accepted—the one which I considered most logical—can no longer, as I have shown you, be regarded as satisfactory. It is perhaps better to have a new one which is reasonable than to remain helplessly at sea in this intricate field of research.

The Relationship of Oral Secretions to Dental Caries.

I. Methods of Determining the Amylolytic Index of Human Saliva.

By HERMANN PRINZ, D.D.S., M.D., Philadelphia, Pa.

From the Laboratory of Pharmacology, Evans Institute, University of Pennsylvania.

INTRODUCTION.

THE most important functions of human saliva consist in moistening the linings of the oral cavity, lubricating the food bolus, washing away the food débris, and chemically altering the insoluble starches of our foodstuffs into soluble sugars. Saliva is a digestive juice. The chemic action of saliva is primarily dependent upon the presence of certain ferments, among which amylase, and to a less extent maltase, catalase, and oxydase are the important ones. The most active ferment is amylase, commonly known as ptyalin or as diastase, which in connection with the less active maltase is principally concerned in the cleavage changes of the starches, while the functions of catalase and oxydase are as yet doubtful. The digestive action of human saliva was first discovered by Leuchs in 1831, and further investigated by Schwann. Berzelius in 1840 named the organic constituent of saliva ptyalin, and Mialhe and Cohnheim in 1865 were able to isolate this product in a comparatively pure form. The amylase of human saliva is practically identical with that obtained from vegetable sources (malt), although they differ slightly in their optimum action. Vegetable amylase is usually referred to as diastase.

GENERAL DEFINITION OF FERMENTS.

According to our present conception we may define a ferment as an organic

substance produced by the living cell which, in its general behavior, is closely allied to a catalyzer, *i.e.* a substance which by its mere presence possesses the faculty of markedly increasing the velocity of chemic reactions, which as such usually occur only extremely slowly. Incidentally, during its activity the ferment is not altered, and it does not form an integral part of the final product. Apparently, ferment action is specific in its nature; that is, a ferment acts only upon a substance having a definite stereochemic configuration to which the specific ferment is adjusted, or, as Emil Fischer has most fittingly expressed it, the ferment conforms to the substratum, *i.e.* the substance to be acted upon, in a somewhat similar manner to that in which a key fits a lock. Ferments have been and to some extent are still referred to as enzymes. The latter term is employed to designate so-called unorganized ferments, *i.e.* purely chemic substances as separated from the organic "living" ferments. At present this conception is obsolete, since it is possible to separate the enzymes from the mother substances by simple powerful physical means (Buchner press). Relative to their physical nature, ferments are closely allied to colloids; however, one of the prime requisites of a colloid, *i.e.* the property of passing through animal or vegetable membranes, is not fully shared by them.

Numerous ferments are produced or

secreted by the mother cells in an inactive form. Such ferments are known as pro-ferments, or enzymes. These pro-ferments require for the exhibition of their full activity the presence of another body, *i.e.* an activator. These latter substances may be purely chemic substances, as acids, alkalis, or salts, or they may be in the nature of substances closely related to the ferments themselves, and known as co-ferments or kinases. Again, certain substances are known to check the action of ferments in a manner analogous to that in which the activator enhances their activities. These substances, being either purely chemicals or ferment-like bodies, are known as anti-bodies, anti-ferments, or paralyzers. In general it may be stated that ferment action stops as soon as the products of its own action have reached a certain concentration.

NOMENCLATURE.

Unfortunately, at present the terminology of ferments is found to be still in a somewhat chaotic condition. The various terms applied to different ferments by the older investigators, owing to the immature state of biologic knowledge, were largely arbitrary selections which may or may not have been suggested by some apparent action of the ferment, or the selected name was simply a modification of that of the substance from which they were obtained. For instance, the term diastase, which signifies a separation, was employed to indicate the principal ferment of saliva, as it possesses the power of reducing or separating sugar from starchy food. Again, the same saliva ferment is more frequently referred to as ptyalin, a name given to it by Berzelius, indicating a substance obtained from *ptyalon*, the Greek equivalent for saliva. At present, it is customary to refer to this substance in conformity with accepted modern ferment terminology as amylase, *i.e.* a ferment which reduces starch. Modern ferment nomenclature is based upon the principle of adding the suffix *ase* (from *asis*, slime or colloidal substance) to the

Greek or Latin root of the substratum, which in this case is *amylum* (starch).

METHODS OF DETERMINATION.

The various analytic methods employed for the purpose of determining the amylolytic (starch-converting) power of saliva are either qualitative or quantitative in their nature, and are based on chemic or biologic reactions of the intermediate or the end products of the cleavage action of the contained ferments upon carbohydrates. The more important methods may be enumerated as follows:

That of estimating the resultant sugar by means of Fehling's solution (Lintner) or by titration (Bang).

That of estimating the quantity of reduced glycogen by polarization (Pflueger; Bang).

That of estimating the quantity of reduced starch by test plates (Mueller) or by glass tubes (Walther; Mett).

That of estimating the quantity of reduced starch by geometric rotation (Wohlgemuth).

In determining the relationship of human saliva to dental caries we are interested principally, aside from numerous other questions, in the quantitative changes of the starch contents of carbohydrate foodstuffs collected about the teeth. These changes depend primarily upon the action of certain ferments present in the oral secretions; hence the importance of determining the amylolytic index of saliva. Any method which offers quick and reliable comparative results is suitable for the purpose in view. Basing our choice upon extended experimental work, we have finally selected the Wohlgemuth rotation method for this specific purpose, on account of the simplicity in regard to the apparatus employed, its reliability, and the small expenditure of time.

CLEAVAGE OF THE STARCH MOLECULE.

When complex carbohydrates, especially starches, are subjected to the influence of certain specific ferments, as

amylase, for instance, in the presence of water and a suitable temperature, a process of hydrolysis of the insoluble starch paste is inaugurated which results in the progressive formation of soluble bodies closely allied to sugar. Brown and his co-workers assume that the hydrolyzation of starch occurs in a step-like fashion and that at least eight distinct phases of this process of reduction may

The final products of the starch cleavage are as yet not definitely known. With the creation of each individual lower dextrin, incidentally a certain quantity of maltose is produced. The amount of maltose progressively increases during the process of transformation of the starch into dextrins. Graphically, the various phases of the above changes may be represented by the diagram shown.

be observed. The complete chemic process of the cleavage of the starch molecule is by no means definitely settled; however, the presence of the products of this cleavage action may be distinctly revealed by a series of colorimetric changes brought about by the addition of certain chemicals, especially iodine, or by other chemic or physical means.

When iodine solution is added to a mixture of starch and water, an indigo-blue color is produced in the presence of hydriodic acid or an iodide, which color, while not permanent on boiling, reappears temporarily on cooling. This same color reaction is revealed by the first product of the cleavage process, *i.e.* amylo-dextrin, also known as amidulin or more commonly as soluble starch. Incidentally with this change into soluble starch, the opalescence of the starch mixture disappears. The next product within the cycle of cleavage is erythro-dextrin, which is manifested by a Bordeaux-red color in the presence of iodine, and this, in turn, is followed by achroo-dextrin, a compound which, as its name indicates, does not react colorimetrically.

METHODS OF COLLECTING SALIVA.

Human saliva represents the mixed secretions from three pairs of salivary glands and the minute mucous glands distributed about the oral cavity. If, for specific physiologic experiments, it be desirable to obtain saliva from a single gland, it may be accomplished by introducing a sterile catheter into the opening of the respective gland duct (Astaschewsky), or the saliva may be collected by means of an apparatus known as a segregator (Pickerill), or it may be pumped out of the gland by means of a suction cup (Howe).

For the purpose of determining the amylolytic action of the mixed saliva it is essential to obtain the combined secretions of the oral glands in the resting stage of digestion. Hoppe-Seyler's method of collecting the mixed fluid from the mouth is best adapted for such purposes. Artificial teeth, if any, should be removed, and the patient directed to wash out the mouth thoroughly with water. After the lapse of about a minute the patient is instructed to bend his

head forward and open his mouth wide so as to allow the saliva to drip into a clean glass. To facilitate the flow of saliva, masticating movements with the jaws are usually helpful. The chewing of paraffin, rubber, etc., or other forms of stimulation, as the vapor of acetic acid, ether, etc., are to be avoided. No sucking motion should be employed, as this may tinge the saliva with blood, which materially alters the amylolytic power of its amylase content. The normal adult healthy individual produces during waking hours approximately 1 cc. of saliva per minute. This quantity, however, varies greatly, depending upon chemical, mechanical, electrical, thermal, and psychical impulses in the form of stimuli, and upon individual characteristics of the patient.

Saliva is a digestive juice secreted by the oral glands. The secretory functions of the glands adapt themselves to the nature of the various stimuli (mastication, foodstuffs, and psychic impulses), and consequently the respective chemical composition of saliva depends primarily upon the nature of these stimuli. Saliva which is collected for the specific experimental work under consideration should be obtained during the resting stage of the glands, *i.e.* about three hours after mealtime and never before breakfast. These requirements are in harmony with the usual methods employed in obtaining gastric juice for chemical analysis.

PROBLEMS OF INVESTIGATION.

The problem which confronts the investigator may be stated as follows: How many cubic centimeters of a 1 per cent. starch solution are reduced to sugar by 1 cc. of a given ferment solution at a specific temperature within a definite period of time? The obtained results may be defined as the amylolytic index of the ferment solution under consideration, and may be expressed by the letters A I. The substratum (starch solution) may be represented by the letter S, and the ferment solution by the letter

F. To obtain the amylolytic index, the quantity of the substratum has to be divided by the quantity of the ferment solution, which, expressed as a symbolic formula, reads:

$$\frac{S}{F} = AI$$

Incidentally, the exact temperature expressed in degrees C., and the exact period of time necessary to accomplish the reaction, expressed in minutes, is noted. The temperature most suitable for developing the optimum activity of human saliva is, naturally, body temperature; *i.e.* 38° C., while the standard of time required to bring about the amylolytic change in 5 cc. of a 1 per cent. starch solution may be fixed at 20 minutes. Consequently, the amylolytic index may be expressed by the following equation:

$$AI \frac{38^\circ}{20} = x$$

—*x* representing the number of cubic centimeters of a 1 per cent. starch solution reduced by 1 cc. of a definite ferment solution at 38° C. within 20 minutes.

To obtain the necessary standard solutions of saliva (ferment solutions), it is necessary to dilute the normal saliva in such a manner that any geometrically diluted portion will be *n* times weaker than the preceding portion. To accomplish this procedure in a most convenient manner, the method suggested by Wohlgemuth is most satisfactorily employed. It is known as the rotation method, and applied as follows: Ten perfectly clean and dry test tubes of equal length and diameter are selected, placed in a test-tube rack and marked with figures 1 to 10 in rotation with a wax pencil. Tube 1 receives 1 cc. of undiluted saliva, while each additional tube receives 1 cc. of distilled water. Tube 2 receives in addition 1 cc. of the same undiluted saliva as tube 1. With a suitable pipet of one cubic centimeter capacity, divided into tenths, this saliva mixture is drawn into

* 1 cc. of contents of tube 10 being discarded as waste.

the pipet and expelled back into the test tube. This maneuver must be repeated three times to insure perfect mixing. Exactly 1 cc. of this saliva mixture of tube 2 is now transferred by means of the same pipet to tube 3. The same maneuver of mixing and transferring the diluted saliva as contained in tube 3 is repeated, and so on until finally tube 10 is reached. Again, 1 cc. of the mixed saliva of this last tube is withdrawn and discarded. Each one of the ten tubes should now contain exactly 1 cc. of fluid; the amount of saliva present in each tube differs exactly by 100 per cent. from its right or left fellow, as may be easily ascertained by reference to Table No. 1.

PREPARATION OF THE STARCH SOLUTION.

One gram of so-called soluble starch (Lintner) is carefully weighed off, transferred to a porcelain capsule or casserole, and thoroughly mixed with 100 cc. of cold distilled water. The mixture is then heated with constant stirring until a perfectly clear solution is obtained. After cooling, the solution, if not perfectly clear, is filtered into a graduated cylinder, and the lost portion of the water is replaced by fresh distilled water. The completed solution is transferred to a clean glass-stoppered bottle. This starch solution, if kept at a cool temperature, will remain unchanged for about a week. The addition, to aid preservation, of chloroform, toluol, etc., is not to be recommended, as there is always a liability of precipitating the starch.

PREPARATION OF DECINORMAL IODIN SOLUTION.

Decinormal iodine solution should preferably be obtained from chemical supply houses, or it may be prepared as follows: Dissolve 12.653 grams of dry iodine U.S.P. in a solution of 18 grams of potassium iodide U.S.P. in 300 cc. of distilled water. Then add enough water to make the solution measure at ordin-

ary temperature exactly 1000 cc. Transfer the solution to an amber-colored glass-stoppered bottle and keep in a dark place. For testing the starch solution under consideration, a conveniently small quantity of the decinormal iodine solution should be diluted with nine times its volume of distilled water. This N/100 iodine solution preferably is kept in an amber-colored dropping bottle.

TECHNIQUE IN DETERMINING THE AMYLOLYTIC INDEX OF SALIVA.

Solutions required.

- (1) Ferment solution.
- (2) 1 per cent. soluble starch solution.
- (3) Distilled water.
- (4) N/100 iodine solution.

Ten test tubes are placed in a test-tube rack and numbered in rotation with a wax pencil. The first tube receives 1 cc. of the saliva to be tested; the other tubes receive 1 cc. each of distilled water. The second tube now receives in addition 1 cc. of the same saliva. In accordance with the directions given above, the saliva solution of the remaining tubes is now geometrically diluted so that each tube will contain 100 per cent. less saliva than the preceding tube.

With a suitable 5 cc. pipet, each tube will now receive 5 cc. of the 1 per cent. starch solution, starting with the tube which contains the smallest amount of saliva, namely, tube 10.

The ten tubes are at once transferred to a suitable water-bath having a constant temperature of 38° C. This water-bath consists of an ordinary enameled metal dish, about 8 in. wide and 4 in. deep, placed upon a suitable tripod. To hold the tubes in position, a wire basket such as is used in bacteriologic work is placed in the dish together with a centigrade thermometer. The dish is filled with tap-water to within an inch from the top, and the water is heated to 38° C. By lowering the flame sufficiently, the water is kept constantly at the above temperature. The test tubes must be immersed in the warm water

in such a manner that the surface of their contents will be slightly below the surface of the surrounding warm water, to insure uniform heating.

The tubes are left in the water-bath for exactly 20 minutes; they are then removed, and each one is filled at once with cold tap-water to within an inch of its rim and is placed in numerical rotation back into the test-tube rack. The cold water will interrupt the ferment action. Each tube now receives 5 drops

will be observed that an intermediate tube in the routine color sequence exhibits a color in which the reddish shade predominates over the blue. In such cases it is best to add one or two more drops of the iodine solution. If the resultant shade is now more blue than red, the tube is classified as containing unreduced starch, while if more reddish in character, it is classified as containing reduced starch. The tube containing the Bordeaux-red color is referred to as

TABLE 2.—AMYLOLYTIC INDEX OF SALIVA.

| No. of tube. | Saliva. | H ₂ O. | Starch 1 per cent. | Time. | Temperature. | Iodin sol. N/100 | Amylolytic index. |
|--------------|-----------|-------------------|-----------------------|-------|--------------|---------------------|----------------------|
| 1 | 1 cc. | 0 cc. | 5 cc. | 20' | 38° | 5 min. | 5 |
| 2 | 0.5 cc. | 0.5 cc. | " | " | " | " | 10 |
| 3 | 0.25 cc. | 0.75 cc. | " | " | " | " | 20 |
| 4 | 0.125 cc. | 0.875 cc. | " | " | " | " | 40 |
| 5 | 0.062 cc. | 0.938 cc. | " | " | " | " | 80 |
| 6 | 0.031 cc. | 0.969 cc. | " | " | " | " | 160 |
| 7 | 0.016 cc. | 0.984 cc. | " | " | " | " | 312.5 |
| 8 | 0.008 cc. | 0.992 cc. | " | " | " | " | 625 |
| 9 | 0.004 cc. | 0.996 cc. | " | " | " | " | 1250 |
| 10 | 0.002 cc. | 0.998 cc. | " | " | " | " | 2500 |

of the N/100 iodine solution, starting with tube 10. A definite color reaction can be observed at once. The higher-numbered tubes, say 8 to 10, will usually exhibit a deep blue color, tube 7 a bluish-red and tube 6 a Bordeaux-red color, tube 5 a brownish yellow color, while tubes 4 to 1 will show a very slight yellow color. The colorimetric manifestations indicate the reaction between the iodine and the starch solution. Completely reduced starch (maltose) gives no color with iodine. This is equally true of achroë-dextrin, while erythro-dextrin produces a Bordeaux-red color. The unaffected starch shows a blue color. (See colored plate.) Occasionally it

happens, that is, the border line between reduced and unreduced starch, and the next tube lower in the scale (brownish-yellow color) furnishes the basis for obtaining the amylolytic index.

ESTIMATING THE AMYLOLYTIC INDEX.

To express the amylolytic index as deduced from the results of the above tabulated experiment, it is necessary to divide the quantity (5 cc.) of the starch solution employed by the absolute quantity (0.016 cc.) of the saliva employed. The resultant quotient represents the number of cubic centimeters of a 1 per cent. starch solution which are reduced

by 1 cc. of the saliva within 20 minutes at a temperature of 38° C.:

$$0.016 \div 5 = 1 \div x$$

$$x = \frac{5 \times 1}{0.016} = 312.5$$

To eliminate loss of time in figuring the amyolytic index in each individual experiment, the accompanying ready reference table will be found serviceable. (See Table 2.) In using the table, read

off the number of the tube in the test-tube rack containing the *limes* of the experiment under consideration, and select the next lower tube as the base for the mathematical equation. By referring to the first column of the table, which represents the tubes in numerical sequence, we find that the amyolytic index of each tube is represented by a definite figure in the last column.

(To be continued.)

40TH AND SPRUCE STS.

Possible Relationship of Oral Focus to Chronic Osteomyelitis.

(A Case Report.)

By M. HILLEL FELDMAN, D.D.S., New York, N. Y.,
DENTAL SPECIALIST, LINCOLN HOSPITAL, NEW YORK CITY.

SCIENTIFIC investigations to determine the exact relationship existing between systemic disorders and oral foci seem to be resulting in the collation of no small amount of evidence which

age, presented at the dental operating room of Lincoln Hospital with the following history:

About twenty-one years ago the patient suddenly experienced a series of stub-

tends to lay responsibility for many ills at the door of the oral cavity. The case which the writer reports here is very interesting in this connection.

Some six weeks ago, at present writing, the patient, male, thirty-six years of

born pains in his right leg. The surgeons at Mt. Sinai Hospital diagnosed his case as osteomyelitis, and when minor treatment availed nothing the leg was amputated at the hip joint. During the succeeding years the patient has been

operated upon some thirty-odd times in various parts of the body—the left leg, both elbows, both arms, shoulders, left side of the stomach, and on the left side of the face at the lower border of the mandible for osteomyelitis of the jaw.

For a number of years the patient has had pains in the left cheek-bone and left great toe. The latter pain he has had incessantly, dull and persistent, for over twelve years.

The mouth of the patient was radiographed and it was found that considerable rarefaction was present about the lower incisors. The accompanying radiograph illustrates the condition of the tissues surrounding the teeth. There was no indication in the regular examination of the patient's mouth to cause suspicion to rest upon these incisors.

Our findings only emphasize the absolute necessity of roentgenographic determinations to supplement our clinical findings.

Extraction of the six lower incisors, followed by removal of the necrotic alveolar and bony tissue and polypi resulted in what I consider to be a remarkable recovery. The pains about the cheek-bone and great toe have disappeared completely.

When we take into consideration the fact that no attempt had been made to relieve the patient by means of autogenous vaccines, we cannot but come to the conclusion that we have found the focus of infection which was draining its toxins into the blood stream these many years.

1339 PROSPECT AVE.

CORRESPONDENCE

Dental Service in France.

TO THE EDITOR OF THE DENTAL COSMOS:

Sir,—After wishing for many months to be able to go to France for service in the Dental Corps, and trying in many ways to secure an opportunity, finally the chance came, and almost before I realized it I had landed at Bordeaux and was on my way north to Paris. It was bitter cold, everywhere there was a shortage of coal, and I was very thankful when the hospital was reached.

Our hospital lies in a beautiful, peaceful valley. One can hardly realize that within a little over a hundred miles away the greatest war in the world's history is going on. Quite frequently we hear the heavy guns booming out their messages of death and destruction.

But my thought is to give you an idea of the French soldiers' mental atti-

tude toward dental work and the prophylaxis and conservation of their teeth. In a way they are just like children; they are sufficiently bright, but they have never been taught that it is for their own personal good to care for their teeth.

I recall one instance where a man was badly wounded in the thigh; the wound failed to heal, and finally the surgeon in charge asked me to look at the man's mouth. There I found eight or ten badly broken-down and decayed roots, and of course an abscess on the end of each root. The roots were extracted, and in a week's time the wound in the thigh had healed. The soldier thought it a miracle, but it was only relieving the blood of organisms that it could not handle. That man's attitude toward dentistry changed at once. He had be-

fore had the idea that dentistry always meant pain, and had laughed when told that his mouth must first be put in a cleanly condition before his wound would heal; but when he saw the results on his own body his astonishment and gratitude were unbounded. Not only did he report to me every week and show me how he was caring for his remaining teeth, but he passed the word along to others, and he was never happier than when he could bring a new patient to me.

In the case of new patients, if there is extensive extracting to be done, they must be told that plates will be given them after their mouths have healed. This they never seem to realize, and almost always ask what they will eat with, if their teeth—or rather the remains of their teeth—are extracted. Some of the men absolutely refuse to go to the dentist.

There was one case in which a man was badly in need of dental attention, but refused to go to the dentist. His mouth had been examined in the ward and he had been told to report in the dental operating room. One night about ten days later he caught cold; an upper cuspid failed to drain, as it had been doing, into his mouth, and the upper right side of his face became swollen, almost closing his right eye. He was frightened, and the next morning reported to me bright and early. The

troublesome root was extracted without delay and in twenty-four hours he was happy again. Two days later, when his dressing was being removed, he asked to have all the decayed roots extracted.

Many of the men have splendid teeth, especially those whose homes have been in the country, but owing to their lack of knowledge of cleaning and caring for them they have become heavily incrustated with tartar, this accumulation of filth pressing and irritating the gingival margins in a shocking manner. After receiving a thorough prophylactic treatment and a talk on how and why they should keep their teeth clean, it is surprising and gratifying to watch the way in which they do what is taught them. In many cases where it has been possible to save the tooth, a root amputation has been performed. This the *blessés* liken to the removal of an *éclat*, or piece of shell.

In the beginning of the war many French dentists were mobilized and sent to fight; undoubtedly this was a mistake, although at the time every man available was needed, and the future for the moment was put aside. At the present time, however, they are being gradually brought back and are now doing splendid and necessary work in the many different hospitals.

F. CORRELL BARTLEMAN, D.D.S.

FRANCE, September 10, 1917.

PROCEEDINGS OF SOCIETIES

Northeastern Dental Association.

Twenty-third Annual Convention, at Worcester, Mass., September 26, 27, and 28, 1917.

WEDNESDAY—*Morning Session.*

THE twenty-third annual meeting of the Northeastern Dental Association was called to order by the president, Dr. David Manson of Burlington, Vt., Wednesday morning, September 26, 1917, at 12 o'clock, in the Bancroft Hotel.

The reading of the minutes of the previous meeting was dispensed with, as they had been printed and copies mailed to the members.

The report of the Board of Censors was read by the secretary, Dr. ALVIN A. HUNT of Hartford, Conn.

The report was on motion accepted.

The Secretary read letters of resignation from Drs. James E. Heap of Providence, R. I., William O. Beecher of Waterbury, Conn., William B. Rogers of Providence, R. I., William N. Butler of Hartford, Conn., and Levi C. Taylor of Hartford, Conn.

On motion of Dr. THOMAS J. BARRETT of Worcester, Mass., the resignations of these gentlemen were accepted.

Dr. BARRETT then made a motion that Dr. Levi C. Taylor of Hartford, and Dr. William O. Beecher of Waterbury, be elected to honorary membership. (Motion carried.)

Dr. HUNT read communications from Mrs. E. I. Bazin, the widow of Dr.

Bazin, who died in 1915, Dr. Herbert L. Wheeler of New York, and Dr. Frederick T. Murlless, Jr., of Hartford.

The report of the Secretary was the next business on the program.

Dr. HUNT. I have no regular report to make, except the communications I have read. I am sorry that we were delayed in getting out the program this year—through no fault of mine. We have had to make some changes in it since it was published. Lieutenant Wheeler's paper will be read on Friday morning, instead of on Thursday evening. On Thursday afternoon, Dr. Tracy, and probably Dr. Asch, will be here to talk on Preparedness. Dr. D. B. Parker of Brooklyn, who was on the program for a paper, will be unable to attend the meeting, having been sent to France. We succeeded in getting Dr. K. H. Thoma of Boston to give us a paper in place of Dr. Parker. Dr. Thoma's paper will be something on the use of anesthesia in oral surgery. Dr. N. B. Nesbitt of Boston, who is on the program for Friday morning, will change places with Dr. Wheeler. Some further rearrangement will probably be called for so far as discussions are concerned.

I should like to emphasize the fact that when members change their addresses, it is desirable that they notify the secretary, because several complaints were made about members not getting

the program, and several programs were returned on account of wrong addresses.

The report of the Treasurer was presented by Dr. LESLIE A. SPELMAN of Hartford, Conn., who had been appointed to fill the unexpired term of Dr. Frederick H. Saunders of Westfield, Mass., Dr. Saunders having been called to service in the U. S. army.

On motion, the report was received and referred to the Executive Committee, acting as the Auditing Committee, to report on it later.

The report of the Editor, Dr. Irving E. Pendleton of Lewiston, Me., being next in order, the President explained that the Proceedings of the association as printed and distributed to the members are usually considered to be the report of the Editor.

Under reports of special committees, the Secretary stated that there was no report from the Committee on Scholarship, Dr. Murlless, chairman, except one of progress. For several reasons the matter had been held up.

The President explained that the matter of carrying out Dr. Cary's suggestion while president in 1916, that provision be made for a sinking or permanent fund for the establishment of a scholarship had been referred to the Board of Censors, but that there was no report to make in regard to it except one of progress.

Dr. HUNT stated that Dr. Saunders had purchased a Liberty bond as a nucleus for this fund. He had asked to have the matter deferred until the last meeting of the Board of Censors, but, in his absence, no report except one of progress could be made until the matter could be worked out by the new treasurer.

Under miscellaneous business Dr. BARRETT made a motion that the secretary send a telegraphic message to Dr. Blake A. Sears of Hartford expressing to him in fullest measure the deep sympathy felt by the members of the society in his grief over the sudden death of his wife. (Motion carried.)

Dr. BARRETT made a motion that the chair appoint a committee of five to bring in a list of nominations of officers for the coming year. (Motion carried.)

The meeting adjourned until the afternoon session.

WEDNESDAY—*Afternoon Session.*

The meeting was called to order by the president, Dr. Manson, at 2.45 P.M.

The President appointed the following as members of the Committee on Nominations: Drs. Thomas J. Barrett, Worcester; W. R. Pond, Rutland; Albert E. Cary, Hartford; Joseph E. Farnum, Providence, and C. Frank Bliven, Worcester.

Dr. MANSON then resigned the chair to the first vice-president, Dr. Ira B. Stilson of Providence, and read the President's Address, as follows:

President's Address.

By Dr. DAVID MANSON, Burlington, Vt.

I esteem it a privilege and a high honor to have been chosen to preside over the deliberations of this meeting of the Northeastern Dental Association, and it is with much satisfaction that I welcome you as members of this great organization of New England dentists.

I also extend a most cordial greeting to all ethical members of the profession, with the hope that our deliberations, essays, and clinics may prove of such interest and profit to them that we may later greet them as members.

It was in this City of Worcester, on October 24, 1895, that the Northeastern Dental Association was formed by the union of the Connecticut Valley Dental Society and the New England Dental Society; and since the Connecticut Valley Society was formed in 1863, and the New England, through the Merrimac Valley, had a like record, we may properly claim that the history of the Northeastern dates from that time. The newly formed Northeastern Association chose as its first president Dr. James McManus of Hartford, who was in 1869,

forty-eight years ago, president of the Connecticut Valley Society, and I doubt if we have today a single member who has an equal record of attendance at our meetings—certainly not one who since the organization was formed has been more keenly interested in all that pertains to the advancement of the association and our profession. The high esteem in which Dr. McManus is held by the members is a deserved tribute to one who has always stood for the highest ideals in private and professional life.

As stated in our constitution—"The objects of this association are to unite in one society the dentists of New England . . . who are members of their respective state societies," etc. In other words, to unite the members of the different state societies in one great New England Association.

In the formation of a new organization one of the most important things is the selection of a suitable name, a name that will be at once suggestive and comprehensive, and expressive of the work that the organization proposes to accomplish. I would not question the wisdom of those who selected the name for this society, but it would seem that the name Northeastern is not at all suggestive for an organization that has for its field of activity a definite geographical section of the country. Northeastern might mean Northeastern Maine or Northeastern Massachusetts; certainly it does not definitely suggest New England. If it were called as it would seem that it should be, the New England Dental Association, I believe that its work would be better understood by many dentists who are not now familiar with it, and would result in an increased membership; and I cannot but believe that in holding to a name that is not at all suggestive of the particular field of our endeavors or expressive of the work of our organization, we are working under a continual handicap in seeking to make it, as it should be, the great dental association of New England. I believe it would be to the advantage of this organization to be known as the New England Dental Association.

DOMINANT FORCES IN THE DEVELOPMENT OF DENTISTRY.

With the birth of dentistry there came into existence the dental college, the dental journal, the dental society, and the dental examining board, and these together may be termed the progressive forces of our profession.

Each of these forces has its own particular sphere of work and usefulness, and it is the intermingling of these influences that has made possible the wonderful progress in dentistry. It would perhaps be difficult to say which of these forces has had the most important part in the advancement of our profession, yet we may safely say that the dental society has had as great a part as any.

The dental college is the principal force in the early or formative period of the dentist's professional life, and dental education has continually advanced by reason of increased requirements for admission, and by lengthened and more systematic courses of instruction. The dental journal is a continual educational force in that it brings to the profession the best scientific teaching and methods of practice. The dental examining board is a constant and compelling factor in that it passes on the knowledge and ability of those who would enter into professional practice, and compels the colleges to properly fit their students before graduating them if they are to successfully pass these boards; yet back of all these forces is the great body of organized dentists as represented in the many state societies, with perhaps its highest expression in the National Dental Association.

It is these organized bodies of dentists who have brought into effect the laws regulating the practice of dentistry in the different states and creating the examining boards, who demand of the colleges that students be given the most advanced instruction in theory and practice, and be properly fitted for active professional life, who demand of the journals that the profession be kept informed as to the most advanced scien-

tific knowledge and methods of procedure. It is the duty of the dental society that it bring before its members the best scientific teaching and the best methods of practice and procedure, and to make its meetings so attractive and instructive as to command an attendance in keeping with the field it covers.

In this respect this organization of New England dentists has a special opportunity and a special duty, namely, to seek to bring the practice of dentistry in New England up to the highest possible standard by conducting each year a meeting along the most progressive lines, and of as high educational advantage and opportunity as it is possible for any other section of the country to hold, and such as it would not be possible for any single New England state to conduct.

If we are to justify our existence as the great dental association of New England we must have something to offer that the state society does not provide.

POSTGRADUATE MEETINGS.

The form of dental meeting is changing somewhat, and in some sections of the country they are holding with much success the so-called postgraduate meetings, where instead of having many essayists to present the different subjects in a limited time, a few paid lecturers are secured, and the subjects considered are presented in a series of lectures covering the entire field, and the clinics are conducted by dividing the convention into as many groups of observers as there are clinicians, each group visiting the different clinics at stated intervals. Where such meetings have been held they have had enthusiastic support, and have resulted in increased attendance and membership.

We want in this New England Association the very best dental meeting that it is possible to have, and we want an attendance and membership such as our territory warrants. If the postgraduate meeting will give us this, it is worthy of our consideration and adoption.

THE DENTAL PROFESSION AND THE ARMY.

The dental profession has responded in a splendid and patriotic spirit to our country's need in the present world war. Throughout the country dentists have given generously of their time and ability to properly fit the mouths of men for service in the army and navy.

Because of this work, rendered wholly from a sense of patriotic duty, many men have been enlisted in the army and navy who would otherwise have been rejected because of poor teeth and unhealthy mouths, and the mouths of large numbers have been put in the best possible condition to properly fit the men for prolonged service at the front. This service has been rendered not in response to any request on the part of the government or of the public, but rather because the profession as a whole, realizing the vital importance to the enlisted men of sound teeth and clean healthy mouths and their bearing upon the general health, and knowing that the government has failed to provide adequate dental service for the army and navy, have volunteered to render to the country and the flag a service that they are particularly fitted to give.

Many members of our profession have enlisted and are enlisting in the dental reserve corps of the army, ready to do their bit and to give up an established practice that they may serve their country and those who are to serve their country.

With the sacrifice that they are making in response to our country's need it would seem proper that those of us who are to remain at home owe it to these men to do everything reasonable in our power to protect their practices during their absence, to care for their patients, and when they return to again take up their private practice we should see to it that in every case their patients are returned to them. I would recommend that this association and every dental society in New England that has not already done so, place itself on record to that effect.

In making a suggestion that affects the different state societies it is not with the thought that this association should in any way seek to dictate the policy of the different state societies, yet we may properly consider it within the province of this association to endeavor to bring about in New England uniform action in all matters that pertain to the well-being and advancement of our profession, and to endeavor to have New England stand as a unit in such matters.

DESIRABILITY OF UNIFORM LAWS REGULATING THE PRACTICE OF DENTISTRY.

With this aim in view we should seek to maintain uniform laws regulating the practice of dentistry. Such laws should be governed by the standards of dental education, and should require of those who would enter practice that they have such professional education as is provided by our recognized dental colleges. When such a condition does exist, there would seem to be no good reason why reciprocity should not be established, in New England at least. There can of course be no reciprocity except between such states as have laws of the same standard, and that standard should be based on educational requirements. If in New England we can bring about an interchange of licenses based upon uniform educational requirements, the influence of such action should do much to establish reciprocity throughout the country.

I trust that this meeting may prove of such interest and profit to every member as to repay him for being present. The fact that our country is at war has made it difficult to prepare a satisfactory program, but we feel that we present a program that should command your approval—one of exceptional interest and educational value, the essayists and clinicians being men of the highest professional attainment and particularly qualified to present the different subjects.

DISCUSSION.

Dr. W. R. Pond, Rutland, Vt. *Mr. Chairman, and fellow members of the*

Northeastern Dental Association,—I can think of only one reason why I was chosen to open the discussion on the President's Address, and that is that I am from the same state as Dr. Manson. However, I very much appreciate the honor, and wish to congratulate him on his most excellent address. I thoroughly agree with him in regard to the desirability of a change of name for this society. Of course its members all know what the Northeastern is, but in other parts of the country, if you mention its name, it does not mean anything particularly. I think that the "New England Dental Society," as Dr. Manson has suggested, would therefore be a much better title.

Now as to the field of this society. As Dr. Manson says, unless it can produce something that is better than the state societies produce, this society has but little excuse for existence. It should have a very large membership. Judging from the treasurer's report, we have now considerable money, and I do not see why we cannot have meetings that will be attractive enough to make everyone feel that he cannot afford to miss them. I believe that the postgraduate system of meetings would appeal to our members as something different from the state meetings.

Dr. Manson speaks about the dental colleges, the dental journals, the dental societies, and dental examining boards associated with the birth of dentistry. It seems to me that the birth of almost all of these things mentioned was the result of a spirit of commercialism, which I am glad to say we are getting away from. I can remember when the dental colleges, for instance, were run quite as money-making schemes. Those who ran them got the residue after all the expenses were paid, and I know of one man who is reputed to have made half a million or so out of dental education. It is fine that we are getting away from that, but we have many things yet to improve with regard to dental education. I believe that as dentistry is a specialty of medicine, the ultimate result will be that the dentist will have to have an M.D. degree or at least that his preliminary educa-

tion will be the equivalent of a medical course, and he will then specialize in dentistry.

The journals have been in somewhat the same condition. Our trade journals have served a very valuable purpose, but it is gratifying to know that we now have independent magazines, like our *National Journal* and the *Journal of the Allied Dental Societies*.

The dental societies have been a great educational factor. After all, in the words of the prize ring, the college course is only a preliminary bout. It must be along the right lines. We must have the proper foundation, but it is what we do afterward, in following up our studies, that counts in the long run. I know of men who never saw the inside of a dental school who have worked hard and improved themselves, and are much more competent and better educated men than those who have gotten a dental degree in a few months, and who think that it is sufficient to last the rest of their lives. It is better to build a house on a good foundation, but you can jack the house up and put a good foundation under it afterward, and make a respectable dwelling of it. I think that applies to dental education as well.

The dental examining boards probably have done a great deal. They are doubtless what we might call a necessary evil; I happen to be on one of them, and so I can say this without criticism. It seems as if the colleges should fit men to practice their profession without their graduates having to go before an examining board. Such is not the case, however. I often wonder how in Heaven's name some of these men slip by the colleges, when I see the way they appear before the examining board. At the present time, we do seem to need to examine these men, to keep them up to the necessary standard and to try to raise the standard for the colleges.

The matter of reciprocity between states would be quite ideal. In Vermont, we have reciprocal relations with about eight states, so far as I remember now. There are some conditions, however, that might be improved. For instance, we

cannot reciprocate with New Hampshire, because they allow men to take the examination without a dental degree, and Vermont requires them to be graduates in dentistry before taking the examination. I hope that this will soon be remedied, so that the requirements may be uniform throughout New England, at least. I remember receiving a long letter from a dentist in the northern part of our state, complaining that some men came in there by virtue of reciprocity and practiced in the summer. I did not pay much attention to this, but a year later, I had another letter from the same man, saying that his health was not very good and that he would like to go to California to practice, and stating that he would like to have the advantage of reciprocity. He had a young man with him from West Virginia who was desirous of taking his practice. Although this man had objected to others coming to Vermont in the summer and taking his patients, he was glad to take advantage of reciprocity when it suited his own interests to do so. That is just one phase of the subject.

It is a good thing to take an account of stock, so to speak, to find out our weaknesses, and to think over what dentistry has accomplished. We are told, at the present time, that dentists have done wonderful things in the war, and have received well-earned recognition. Well, some of them have, but are the rest of us prepared to do the same remarkable work in oral surgery, plastic surgery, restoration, etc.? We are not. I say this emphatically. We must all increase our knowledge; we are expected to do great things. It has been said that the next great step in preventive medicine must come from the dental profession. We must do more hard work before we are ready to be absorbed by the medical profession, which is waiting patiently to take us in, when we are fitted. We are doing great things in the army, and I trust that we shall get recognition for it and an increase in rank, so that some of the older men can go into the army and do good work. Just now it is the younger men who have enlisted,

I think, as Dr. Manson says, those who go in should get all the protection that we can give them. We should not stay home to make the most that we can out of our opportunities to get our brother's practice.

Dr. Manson speaks about promptness in attendance at the meetings. That is very important. In our State Society meeting we always have the same trouble in getting the men there on time. Common courtesy dictates that we should be here promptly, and I hope that we shall have a larger attendance later in the afternoon, to hear Dr. Miner's paper. I have heard one on the same lines from him, and it was well worth hearing. We should follow up his subject, and have a comprehensive knowledge of oral conditions as influenced by the general health.

Dr. Clinton W. Strang, Bridgeport, Conn. I think the paper has touched upon points that we may well heed, and not only heed, but act upon. Times have changed wonderfully, and unless we conform ourselves to them and plan to meet conditions, we shall be on the down grade. The dental profession has made marvelous advances in every department. When we consider the conditions that existed years ago, when the speaker began to practice, we can hardly fail to wonder how we got along as well as we did.

While I am on my feet, perhaps it might be interesting to you if I entered a little bit into history. Fifty years ago next month I became a member of the Connecticut State Dental Association, and as a member of that association, became acquainted somewhat with the guiding minds of the dental profession in other parts of the country—Atkinson, Varney, and our dear old hero of prophylaxis, Riggs. Most of the older members of the profession have passed on. There are but few that I can think of at the present time who have not laid down their dental instruments. Dr. Gaylord of New Haven is still quite active at the present time, I believe, but I do not know of any other dental practitioner in New England who has devoted fifty years to the practice of his profession and is still in active practice. I have much to

be thankful for, but a great deal that has come to me has been through the generosity of other men better known in the profession than myself, and my commission at this time is to pay a tribute to a man who for fifty years has been a brother, if not in the flesh, yet in sympathy and in a disposition to assist all with whom he became acquainted. I refer to Dr. James McManus of Hartford. (Applause.)

Many there are who have won the admiration of men, who by deed or quality have won the confidence of their fellows, but men regard Dr. James McManus as a brother. There is about him a genuineness that has won men and held them. He is, in every thought and feeling, a man, and yet you will agree with me that he has a heart as tender as that of a woman, and as guileless as that of a child.

In early manhood Dr. McManus made his impress on all about him. He learned the lesson of combining fervor, zeal, and enthusiasm with broad charity and sanity. The only life worth living is the life of the man who works, the man who strives, the man who does, the man who can say, "I know I have faltered; I know I have stumbled; I have left undone things that should have been done, and much that I have done had better been left undone; but, as strength was given me, I have striven to use it; I have striven to make the world better because I have lived in it."

And now I would suggest that a telegram of greeting and good-will be sent to Dr. James McManus of Hartford. (Applause.)

Dr. Stilson. I am not sure that just at this moment the motion will be in order. Discussion of the President's Address is before us now. This motion can be acted on later.

Dr. Thomas J. Barrett, Worcester, Mass. I had no intention of discussing the President's address, but it is such an excellent one, exhibiting so much thought and covering such a variety of subjects, that it is not fair to pass it without comment.

The first thought in the address that

impressed me was the matter of a change of name for this society. The president has certainly presented a good argument for an alteration, and has caused thought to be given as to the wisdom of adopting a new name. Many times since the convention was advertised to be held in Worcester, I have been asked what the association was, and what territory it covered. As the president has said, it is an association of dentists of the states of New England. That being true, it would seem that we could find a name better suited than the Northeastern, as that is very indefinite as to meaning. I think it a matter that could well be taken up and considered by a committee, with the request to report later.

Another matter that I might say a word on is the question of reciprocity so earnestly referred to by our president. It is a subject that has been discussed for years, and treated from various viewpoints by various men. No one can so well understand the safeguards that are necessary before new laws are adopted and old ones changed as those who serve on state boards, and meet the candidates and know something of their history, their character as practitioners, and their ability as professional men. Most of you know the law only as practitioners. We who occupy official positions, who meet and have to deal with the men who are desirous of coming into the state through reciprocity, are better informed as to the safeguards with which we should surround the people than are you. No well-qualified practitioner of dentistry should have any trouble in transferring his labors from one state to another. Dental laws are not intended to prevent or hamper the worthy and capable man, and rarely ever do so. They are, in fact, police regulations of dentistry enacted solely to protect the public from incompetence and ignorance. There are no two states in the Union that have exactly the same laws or require the same tests in examination. There are many that are quite similar, but no two boards exact from the individual candidate the same tests. If a man is engaged in the practice of dentistry as his life's occupa-

tion and means of livelihood, it does not seem to me to be any hardship for that individual to be asked to demonstrate by some fair test, such as a filling operation, his ability to do that work. He is requesting the privilege of going into the state to do that work, and wants a license to do it, a permit to do it among all the people. Now, then, to demonstrate before a fair board his ability to do that is not a hardship; on the other hand, it is a fair provision of protection for the people. It is no hardship for any tradesman or for any specialist in any line of endeavor to be asked to demonstrate his fitness and his ability in his particular line. The Massachusetts Board has for years required that of every practitioner who desired to come into the state. There never has been a case—I say *never*, and I will not qualify it at all—of a deserving practitioner of standing in the community from which he came, who brought credentials as to his ethical practice and honesty of purpose, who experienced any difficulty in meeting the requirements of the Massachusetts Board; the incompetent and the charlatan have.

The board never submits a practitioner of years to the same test as the recent graduate, fresh from his studies, but it does exact and expect from the dentist who has been in practice for five years or longer that he demonstrate by a filling operation his ability to do dental work as a man should after having spent that length of time in practice. From a single operation the members of the board have been able to decide as to his fitness, the balance being always in his favor, I might say. The character of his work might not measure up to what we expected, but if it is done with care and shows a degree of skill, if it shows that he has practiced, and that he may be regarded as a safe man, we license him. We never subject him to a hard or unusual test. I think before the profession goes on record as saying that we should have national reciprocity by law and waive all tests, they should understand what the state boards are trying to do for them as well as for

the public. To let down all barriers and restrictions and waive all examinations would be a grievous mistake, and would open wide the door for the itinerant and unworthy instead of helping the deserving. This is a subject that has been before the National Board of Dental Examiners for fifteen years and longer, and no acceptable solution has yet been found. We must have a nearer approach to a uniform test and a uniform examination, and not have such a wide variance throughout the land, before we can hope for national or even New England reciprocity.

Dr. George A. Maxfield, Holyoke, Mass. With regard to changing the name of the association, I think most of you do not know why we adopted this name when we organized the society. As I was the one who made the proposition to the Connecticut Valley Dental Society and the New England Dental Society to unite and become one society, and wrote the constitution and by-laws, and also proposed this name for the new society, you may be interested to hear the reasons for this movement and why we adopted this name. At the annual meeting of the Connecticut Valley Dental Society in 1892 Dr. L. D. Shepard of Boston read a paper advocating the dissolution of all dental societies aside from the different state dental societies, and uniting all our efforts to strengthen the different state societies. This raised quite a feeling among the members of the Connecticut Valley Society, for at that time the Connecticut Valley Society was the strongest dental society in New England, and the members were very reluctant to consider any such move to break up their society. I agreed with Dr. Shepard that our state dental societies needed all the help they could get, and being a member of the Connecticut Valley, New England, and Massachusetts Dental Societies I made the proposition in 1893 to the Connecticut Valley Society and the New England Society that we consolidate into one. This proposition was agreeably received, and a committee was appointed by each

society to arrange the details and present their plan at a union meeting to be held here in Worcester in 1894. The committees appointed me to write a constitution and by-laws to present to the new society as soon as union was effected. At that time there was much talk of enlarging the National Dental Association, dividing the country into districts, and having a branch society in each district, and on account of this plan I proposed the name of the Northeastern Dental Association, thinking that when the reorganization was completed we could go in as a body, and be the representatives of that association in this section of the country. We met here in Worcester, a joint meeting of the two bodies, and after hearing the report of the committees both societies voted to unite. The new constitution and by-laws were adopted as well as the new name, and officers were elected, and that was the beginning of this association. Since then a different plan was adopted by the National Dental Association, it having taken in all the different state societies as component parts, which leaves us out in the cold. Individually it does not make any difference to me what name we go under. We have done pretty well for the past twenty-three years under our present name, but whatever changes are made I hope this association will always keep up its organization.

Dr. MAXFIELD then made a motion that a committee of three be appointed to consider the recommendations of the President in his address, and report at a later meeting of the society. (Motion carried.)

Dr. STILSON appointed, as the members of this committee, Drs. C. W. Strang, A. E. Cary, and W. R. Pond.

Dr. MANSON then resumed the chair, and called for a consideration of the motion of Dr. Strang in regard to sending a message of greeting to Dr. McManus. (Motion carried.)

(To be continued.)

Eastern Association of Graduates of the Angle School of Orthodontia.

Eighth Annual Meeting, held in New York City, May 7 and 8, 1917.

(Continued from page 73.)

MONDAY—*Evening Session.*

The evening of Monday, May 7th, was devoted to a banquet to the members and guests of the society.

Following the banquet, Dr. N. W. JANNEY, New York City, gave a lecture entitled "An Experimental and Clinical Study of the Isolated Thyroid Hormone."

[This paper is printed in full at page 133 of the present issue of the DENTAL COSMOS.]

DISCUSSION.

Dr. Milo Hellman, New York. I enjoyed the talk immensely, but I was rather expectant of hearing some other phases in conjunction with this work. Being somewhat acquainted with the literature on this subject, I know there are a number of experimenters who have done some work along the line of the calcium metabolism in conjunction with the secretion of these glands. Fleischmann, who has experimented on the effect of the thyroid gland on the teeth, has brought to light the fact that, in rodent animals, if the parathyroids be removed, certain defects will appear on the rodent teeth; and when thyroid extract was administered, the normal form of the tooth would be restored.

Kranz of Germany has observed that certain vertical or horizontal ridges are found on the teeth of cretins, and by removing the thyroid gland in pigs he reproduced experimentally those marks on the teeth.

I should like to ask Dr. Janney whether he has made any observations on the effects of thyroid deficiency on the skeletal structures or other parts that depend mainly on calcium metabolism.

Dr. Janney. In a talk of this kind it is practically impossible even to touch on the various chapters of this enormous book—this great tome of Endocrinology. One of the most fascinating chapters Dr. Hellman has mentioned in his question, the relation of the mineral metabolism to the ductless glands. Studies similar to those we have made on the carbohydrate metabolism could be made on the calcium metabolism. In our work we have not attempted to make any inroads in this field for lack of time. It has taken years of labor to work out these few principles which it takes but a short time to discuss.

I would be delighted to get some information from your experience along this line. Undoubtedly the thyroid, as well as the parathyroids, exert a profound influence on calcium metabolism. I am inclined to think that other ductless glands also exert a similar influence. I have noticed that the teeth in almost every case of thyroid disease have a softened appearance—I cannot explain it in your vocabulary—but the teeth appear badly worn, and show a lack of proper calcification. This fact is very well known to you. I have no doubt. I have observed the same condition in hypopituitarism. Perhaps you can give me further information on this point. It has suggested itself to me that this may be another example of the synergistic

action of the endocrine glands, or rather its failure.

It is too bad that so little good work has been done on the calcium metabolism and its control by the ductless glands. It is a phase which will probably be worked out in the near future. It needs only the workers to do it. It is a practical subject, as calcium analyses are among the most accurate methods at our command in metabolic work.

Prof. W. K. Gregory, New York. I come into this field from such an entirely different quarter that I cannot make any comment worth while. I might compliment Dr. Janney upon the fact that although I am absolutely innocent of any knowledge of physiological chemistry, I have been able to follow his thought from the beginning to the end to my own satisfaction. It is certainly a difficult matter to make clear to a layman, as I am in reference to this matter, and it has been very helpful to me in this way: As a paleontologist and comparative anatomist, thinking and dealing with evolution in a large museum—the American Museum of Natural History—I have continually brought to my attention the regulation of growth; that is, the fact that there is a certain pre-determination, as it were, in the organism which causes things to stop at a certain point. Our middle finger, for example, is generally the longest, and our thumb the shortest. There are these determinations of growth throughout the organism, and as we follow any race of animals through the geological record—we can follow them through the strata for many thousands of years—we find that this regulation of certain fixed ratios of one part to another changes. That is all that evolution is—a change in the relation of one part to another. I think the same thing has been made clear to many people, that this work on the ductless glands will eventually help us to understand the phenomenon of the regulation of growth, and the secular changes of what are individually fixed relations—that it is all controlled by the ductless glands.

I am sorry that this is such a vague

idea, but it is the only idea from my work that has any bearing on this very interesting paper.

The President. I would like to ask Dr. Janney if the salivary secretion has been taken into consideration in its enzymic action in relation to pancreatic digestion of carbohydrates. I find by closely tabulating the enzymic action of the salivary gland in our work in orthodontia, that as the functional exercise of the organ is increased through our procedure, the stimulation resulting from contact of the teeth and an improved general tone of the body results in an increased quantity of ptyalin, quantitatively analyzed, which has a decided effect on the ferments in feces analysis.

I would like to know if the salivary secretion has been studied at all. We find that in general medicine salivary secretion has held a very small place in the minds of experimenters.

Dr. Janney. There has been practically no work done as yet on the subject Dr. Ferris mentions.

Professor Gregory. May I ask the essayist if his idea is that not one but all these glands control the growth of different parts of the organism. For instance, the size of the jaws, or any other bony element, would any one of these glands have a predetermining influence? According to your polygon, they all seem to have some part.

Dr. Janney. I am glad Professor Gregory spoke of that point, because it has called my attention to a lack of development of that hypothesis of which I have been guilty. I have endeavored by the diagram to express crudely the action of the glands as synergists, that is, the action which, as I have stated, must be ascribed to more than one gland.

Take, for example, the control of the fat metabolism. Persons and animals that have a disturbance in pancreatic action tend to obesity. Evidently the pancreas has something to do with this, and a disturbance of the internal secretion of the pancreas causes it, whether directly or indirectly. But the same holds true in the case of the thyroid;

cretins and young dogs with the thyroid removed grow fat and sluggish. The thymus also exerts a control over the fat metabolism; a hypopituitary patient tends to obesity and mental torpor. This, then, is an action which belongs not to one but to several of the ductless glands. I have used this example to illustrate the synergistic action of these organs.

Aside from this general effect, the endocrine organs have a more definite, localized, or specialized action, which I failed to bring to your attention. For instance, the interstitial tissue has a special control over the secondary sexual characteristics. We have, then, special parts of the body which represent special spheres of control of special endocrine organs. In controlling these local areas, general metabolic processes also play a part. It seems as if one gland might exert the controlling influence, although the others still exercised an effect on the general metabolic processes. Never will these difficult questions be elucidated until we have isolated and properly understand the chemical nature of the various hormones, which is a task of enormous difficulty.

The President. Has Dr. Janney noticed in acromegaly the fact that the inferior maxilla has greatly increased? In two cases of that kind at the Manhattan Hospital, which I have radiographed, the pituitary body was found greatly increased in size. Before our society in Boston we had the opportunity of seeing a skull where the enormous mandible was large enough to envelop the superior maxilla. The case was operated upon, but the patient succumbed under the operation.

Dr. Janney. Of course it is well known clinically that in acromegaly one very definite sign is an increase in size of the mandible. The hands and feet and face are also affected. How to fit that into our theory is very difficult. Have we here a hyper-function, or is it a disturbance of control, *i.e.* a dys-function? This is a very difficult question to answer. Can we in general think of a hyper-function of the ductless glands?

This hypothesis is becoming extremely shaky. We talk of hyper-thyroidism, but why should the thyroid take upon itself the idea of pouring out more of its secretion, when under the law of economy none of the other glands are certainly known to act thus, with the possible exception of the pituitary? Spontaneous hyper-function of an organ is very difficult to conceive, though we have no proof that the cause is extra-thyroid. The heart, lungs, and liver do not spontaneously hyper-functionate. Why should the thyroid?

I question on these grounds, which are merely those of physiologic logic, as one might say, whether acromegaly is a real hyper-function, or whether it does not lie in some distortion of this mutual, synergistic action; whether for some unknown and occult reason the mutual aid has been removed to make an even balance of growth in this case, and that certain of these terminal areas of the osseous skeleton have in that way obtained an undue ascendancy in development over the others, as a result of a dys-function. But this is only a vague hypothesis. The truth is not known.

Dr. B. W. Weinberger, New York. Is there a definite age at which the thyroid becomes more active than the thymus? For instance, up to puberty does a certain activity take place in the thymus, and then recur to the thyroid, or is that a false theory?

Dr. Janney. That, I think, touches upon one of the most interesting phases of the whole question. Of course the facts are perfectly well understood. The thymus is apparently predominant during infancy and early childhood, and then its activity fades away. But the later researchers have found that the thymus tissue does not become absorbed and atrophied, as we were taught as students. There are from one to five grams of thymus tissue which remain quite active even to advanced age. This Matti has shown in a table in his excellent monograph on the Thymus. We have reason to believe in clinical medicine that the thymus may again take on its latent powers of control in this metabolic scheme, because when, for instance, the

thyroid is affected, the thymus increases in size. Surgeons take out such thymus glands; but they remove anything striking them as too large.

This calls to mind a very interesting phase of the matter, and that is the relation of the ductless glands to the growth of the embryo. It is becoming known that, as the embryo grows, certain of the ductless glands of the mother undergo hypertrophy. There seems to be a very definite relation between these phenomena, for if the growth of the embryo is stopped, let us suppose by accident, these glands cease hypertrophying. I speak only of certain cases which have been accurately demonstrated.

Then we come to the control of various parts of the body through what may be production of hormones in the embryo itself at that time; for instance, the stimulatory action on the mammary glands during the period of growth of the embryo in the body. That can be pretty definitely explained now as the result of hormone action. I cannot go into this question, but the farther we go, the more we feel that the general body processes, perhaps even the stature itself, are determined by the endocrine organs

—not that man should grow to five feet eight inches or six feet in height directly according to the law of the Divine Being, but rather according to the law of the hormones.

The President. When are the ductless glands laid down in the development of the embryo?

Dr. Janney. Very early.

The President. One before the other?

Dr. Janney. Unfortunately, the embryology of the ductless glands has as yet been a neglected study, so that I cannot make exact statements as to their relative development. The thymus, thyroids, and parathyroids begin embryologically as endodermic organs. The chromaffin tissue of the suprarenals and posterior lobe of the hypophysis are neuro-ectodermal. The suprarenal cortex, pancreas insular apparatus, and interstitial glands are mesodermal in origin. There seems to be a certain correlation between parts of the ductless glands which are derived from the same germ layer. For instance, the chromaffin tissue of the suprarenals somewhat resembles in function the posterior lobe of the pituitary.

THE DENTAL COSMOS

A MONTHLY RECORD OF DENTAL SCIENCE.

Devoted to the Interests of the Profession.

EDWARD C. KIRK, D.D.S., Sc.D., LL.D., *Editor.*

L. PIERCE ANTHONY, D.D.S., *Associate Editor.*

PUBLISHED BY THE S. S. WHITE DENTAL MFG. CO., PHILADELPHIA, PA.

SUBSCRIPTION PRICE, including postage, \$1.00 a year to all parts of the United States, Hawaiian Islands, the Philippines, Guam, Porto Rico, Virgin Islands, Cuba, and Mexico, Canada, \$1.40. To other foreign countries, \$1.75 a year.

Original contributions, society reports, and other correspondence intended for publication should be addressed to the EDITOR, Lock Box 1615, Philadelphia, Pa.

Subscriptions and communications relating to advertisements should be addressed to the BUSINESS MANAGER of the DENTAL COSMOS, Lock Box 1615, Philadelphia, Pa.

PHILADELPHIA, FEBRUARY 1918.

EDITORIAL DEPARTMENT

Jesse Cope Green.

[SEE FRONTISPIECE.]

If it has happened that any other practitioner of dentistry has rounded out one hundred years of human life having devoted sixty-six years of it to the practice of his profession, is now hale and hearty, blessed with unimpaired faculties, with a spirit verily young, and still looking hopefully toward the future, we have no record of the fact.

Someone has said that old age is merely a numeral; if so it is purely a relative quantity, for in the present instance even the century mark does not represent old age as measured by the vital status of Dr. Green. A man who at seventy-nine first learned to ride a bicycle, rode it daily for exercise until three years ago, and then discontinued its use only at the earnest solici-

tation of his friends, who regarded it as dangerous practice for him, owing to the general use of the roads by automobiles, is not old in any ordinary acceptance of that term.

Dr. Green was born December 13, 1817, of Quaker parentage, and throughout his life has been a consistent member of the Society of Friends. After the completion of his elementary education, in 1836 he became a school teacher at the Friends' School in West Chester. His tastes and mental tendencies directed his attention to the healing art, and for a time he was undecided as to medicine or dentistry as his life-work. Possessed of strong predilections toward mechanical handicraft, he finally decided to select dentistry for his major life-activity, and accordingly began its study with Dr. Mahlon Gallagher of West Chester as his preceptor. In 1843 Dr. Green purchased the practice of his preceptor, which he actively continued without interruption until his retirement in 1900—a period of sixty-six years. The honorary degree of D.D.S. was conferred upon him by the Pennsylvania College of Dental Surgery in 1865.

The span of Dr. Green's active professional life covers practically the period of the whole professional development of this department of art of healing. He began his studies in dentistry about the time of the establishment of the first fundamental factors of our professional organization. The act incorporating the Baltimore College of Dental Surgery, the first dental educational institution in the world, was passed by the Legislature of Maryland March 9, 1840, and its first class, consisting of Robert Arthur and Covington R. Mackall, was graduated February 1, 1841. The first number of the *American Journal of Dental Science*, the first dental periodical in the world, was issued June 1, 1839, and the American Society of Dental Surgeons, the first national dental association in the world, was organized in New York August 18, 1840.

Not only was Dr. Green's entrance into the dental profession contemporaneous with these epoch-making events in our history, but he has been an active and interested participant in all of its subsequent evolution. To the majority of those now living, the series of events that in their totality constitute the history of dentistry are known only as they have been recorded, or by tradition; to Dr. Green they are matters of personal experience, and to hear

from the lips of this man of phenomenally tenacious memory the recital of the many activities and incidents pertaining to the formative period of professional dentistry in which he was personally concerned is indeed a remarkable experience.

His point of view with relation to the development of dentistry is not, however, the only or indeed the most striking feature of his unique life experience. His own history covers the period of most intense evolutionary development of the human race. All of the great achievements of civilization have been accomplished within his knowledge. Steam navigation, the telegraph, all the devices that make for the rapid intercommunication of peoples and hence for civilization, the conquest of the air, the industrialization of humanity, have all taken place within this man's lifetime.

The dental profession throughout the United States have recognized that the centenary of Dr. Green was an important as well as an unusual event, and besides making him the recipient of numberless letters of congratulation and appreciation, the Chester and Delaware County Dental Society gave him a testimonial banquet at which he was the honored guest and center of interest. He was also the guest of honor at the annual banquet of the Chester County Historical Society on the night of his one-hundredth birthday anniversary, on which occasion he made an interesting and vivacious after-dinner talk, showing no signs of fatigue or physical weakness notwithstanding the fact that the same morning he had addressed an audience of upward of one thousand of his townsfolk and the entire day had been given over to receiving the congratulations of his friends.

His good health and longevity he owes to the philosophic calm and cheerful optimism which are his temperamental characteristics. As he has been heard to phrase it, Dr. Green "sheds trouble." He has never used stimulants, and is an indefatigable worker. Since 1857 he has kept an accurate and uninterrupted daily record of the meteorological conditions in his locality, his records antedating those of the Government signal service, and they are now copied in the archives of that bureau. He is a skilled technician, having made anemometers and rain-gauges of his own design for use in his weather observations. He has found time also to construct several fine microscopes, and tradition "hath it" that no better trout rod has ever been constructed than those made by Dr. Green.

The present writer has known him for nearly forty years, has served with him as a colleague on the Board of State Examiners in Dentistry, has had the privilege of contact with him in social and professional ways and in the closer relations of intimate friendship. The youthfulness of his spirit is perennial; his outlook on life is just as optimistic as it always has been. He is an incontrovertible material demonstration of the axiom that life is good.

As the writer views the privilege accorded to himself in the right to number the subject of this sketch among his friends, his regret is that Dr. Green cannot be personally known to all members of the dental profession, and it is just that regret and the desire that a larger number shall know something, at least, about him that must justify this single departure from our editorial policy to exclude personal matters other than obituaries from our pages.

Proposed Legislation for Navy Dental Corps.

THE Legislative Committee of the National Dental Association, under authority of a resolution of the association passed at its late meeting in New York, has prepared a bill providing, for commissioned officers of the Dental Corps of the Navy, the same rank, pay, promotions, and allowances as officers of corresponding grades in the Naval Medical Corps. This bill, designated as S. 3386, was introduced into the Senate by Senator Lodge on January 5, 1918, read twice, and referred to the Senate Committee on Naval Affairs.

The purpose of the bill is obvious. We have secured, after many years of effort, recognition of the status of dentistry by the National Government on a plane of equality with the other medical specialties in so far as dental service in the army is concerned. We must now accomplish the same result with respect to the naval dental service, and with the precedent already established the task should not be difficult. The Legislative Committee asks that members of the dental profession write to the Committees on Naval Affairs of both the Senate and the House, earnestly requesting their support of the bill (S. 3386), and bring such influence as they may be able to command to that end upon

individual members of the committees, the *personnel* of which is as follows:

SENATE NAVAL AFFAIRS COMMITTEE.

| | |
|-------------------------------------|-------------------------------------|
| BENJ. R. TILLMAN of South Carolina. | PARK TRAMMELL of Florida. |
| CLAUDE A. SWANSON of Virginia. | BOIES PENROSE of Pennsylvania. |
| JOHN WALTER SMITH of Maryland. | HENRY CABOT LODGE of Massachusetts. |
| JAS. HAMILTON LEWIS of Illinois. | WILLIAM ALDEN SMITH of Michigan. |
| JAMES D. PHELAN of California. | CARROLL S. PAGE of Vermont. |
| KEY PITTMAN of Nevada. | MILES POINDEXTER of Washington. |
| THOMAS J. WALSH of Montana. | WARREN G. HARDING of Ohio. |
| ROBERT F. BROUSSARD of Louisiana. | FREDERICK HALE of Maine. |
| PETER G. GERRY of Rhode Island. | |

HOUSE NAVAL AFFAIRS COMMITTEE.

| | |
|------------------------------------|------------------------------------|
| LEMUEL P. PADGETT of Tennessee. | ADAM B. LITTLEPAGE of W. Virginia. |
| J. FRED C. TALBOTT of Maryland. | JAMES C. WILSON of Texas. |
| ALBERT ESTOPINAL of Louisiana. | THOMAS S. BUTLER of Pennsylvania. |
| DANIEL J. RIORDAN of New York. | WILLIAM J. BROWNING of New Jersey. |
| WALTER L. HENSLEY of Missouri. | JOHN R. FARR of Pennsylvania. |
| JOHN R. CONNELLY of Kansas. | FRED A. BRITTEN of Illinois. |
| WILLIAM B. OLIVER of Alabama. | PATRICK H. KELLEY of Michigan. |
| WILLIAM W. VENABLE of Mississippi. | SYDNEY R. MUDD of Maryland. |
| CARL VINSON of Georgia. | |

This matter was received too late for insertion of the bill in this issue of the DENTAL COSMOS. The full text will be given in our March issue.

REVIEW OF CURRENT DENTAL LITERATURE

[*Journal of the American Medical Association*, October 20, 1917.]

The Menace of Mouth Infections. By
OLIVER T. OSBORNE.

Osborne is seriously impressed with the potentialities and realities of oral foci of infection. Unfortunately he manifests a sad ignorance of dental thought and practice, and there is a slight suspicion that he is not as sympathetic with the dental profession as some kind words in this article are intended to convey. It would be curious to know to whom this paper was addressed. From its

air of condescension one could believe it was delivered to impress thoroughly upon the dentist and the layman the duty of respectfully deferring to the general practitioner's omniscience on matters dental.

Only two passages contain anything in the least original, and these passages are purely incidental to the main line of the author's argument, viz:

"I find that infected teeth and tonsils are frequent causes of thyroid disturbance. Something irritates the gland, and then something else inhibits the result of its increased activity. This is shown by the surgical re-

moval of the source of the mouth infection. I have seen three such instances. In one case the gland became greatly enlarged after the operation, exophthalmos occurred, and a tachycardia of from 140 to 160 developed. Before the operation absolutely no thyroid symptoms were present except a slightly enlarged gland."

"For now nearly two years, at a public tuberculosis institution, we have examined the mouths, corrected the teeth, and removed the sources of infection of every patient who entered the institution, and owing to this preventive treatment we have had less tonsillitis, fewer sore-throats, less indigestion, and less influenza and colds than we had before we began these mouth investigations."

[*Comptes rendus de l'Académie des Sciences*, Paris, October 15, 1917.]

Regeneration of Bone in the Adult. BY HEITZ-BOYER AND SCHEIKEVITCH.

The classical view of the periosteum as the reparative agent in osseous injuries and losses is controverted by numerous observations afforded by war wounds. In the adult, the property of bone repair or of bone formation is inherent in the bone itself. It is in the irritated bone affected by an osteitis that there arises the process of ossification. This phenomenon in the adult is therefore exclusively pathological—inflammatory—from beginning to end.

Some extensions of these views into the practical fields of war surgery are—(1) If all else goes well it may be unnecessary to remove splinters and fragments of bone too soon from wounds; their presence there acts as an irritant and accelerates the process of repair; (2) on this basis the paradoxical cure of pseudo-arthroses following the development of an attenuated infection becomes understandable; (3) the mechanism of osseous grafts becomes in part more intelligible, where these are known to occur in the absence of periosteum.

[*Pacific Dental Gazette*, San Francisco, September 1917.]

Impressions for Full Dentures, and a Technique. BY G. E. WILSON.

From the modern viewpoint the principles underlying impression-taking may be succinctly stated as follows: With full dentures

as large a base-plate area as possible must be covered, the periphery of the denture must extend upon yieldable tissue sufficiently to form a valve-like contact, and there must be contact with the entire area covered by the base-plate.

In other words, an impression to be satisfactory must insure three things—areal contact, peripheral bearing of the base-plate, and extension upon yieldable tissue.

Areal contact means contact over the whole area included within the periphery of the base-plate, but it does not mean uniform pressure over the whole surface of the base-plate. Areal contact can only be secured by a material that flows. Thin mixed plaster best serves this purpose.

To secure peripheral bearing of the base-plate it is best to reinforce peripherally the impression tray with beeswax, over which there is thin plaster. The wax secures the required compression over the desired portions of the impression, and holds the soft tissues firmly and evenly against their bony foundation.

The essential part of a base-plate to be extended on to yieldable tissue in order to obtain retention is the palatal border from the external portion of one tuberosity to the external portion of the other. The palatal extension upon yieldable tissue should be one-eighth to one-fourth inch in width. The direction for the extensions upon the lower denture is upward and upon the upper denture the extension is downward.

[*New York Medical Journal*, November 10 and 17, 1917.]

A Study of Some Functional Inefficiencies of the Teeth Associated with Occlusal Anomalies. BY MILO HELLMAN.

Hellman summarizes a somewhat extended essay in the form of more or less time-worn conclusions: (1) The efficiency of a denture is dependent not only upon the full complement of teeth in normal occlusion, but also upon each tooth being complete in its form, integral in all its parts, and secure in its attachments to the supporting structures. (2) With the loss of one unit of a denture the functional efficiency is reduced to a vastly greater extent than that represented by the relative numerical proportion of the teeth in that denture. (3) The teeth, though vitally

concerned in the mastication of food, constitute at the same time important adjuncts in the perfection of the functions of respiration and of speech. (4) With every digression from the normal in occlusion affecting the process of mastication, there is also a corresponding deviation from the normal in respiration and speech.

Considered as a part of an educational propaganda among the medical profession, the article doubtless is justified. It contains frequent reference to concrete cases, and is very satisfactorily illustrated by many pertinent models.

[*Journal of the National Dental Association*, October 1917.]

Persistent Chronic Apical Inflammation and Its Treatment. BY JOHN S. MARSHALL.

The value of this paper lies in the novelty of the therein outlined method of treatment—novel only in the sense that it is a method of great rarity today, though at least twenty years ago Marshall made it public. The title of that early paper clearly tells the story: "A Plea for the Extraction and Replantation of Teeth for the Cure of Persistent Alveolar Abscess."

The instruments required for this operation are a dental engine, 1 pair of forceps, 2 curets—1 straight, 1 curved—1 one-half inch carborundum stone, 1 spear-pointed drill, and 2 round burs.

Previous to the operation an impression is taken of the region of the tooth in question, and a swaged splint is prepared. Great care must be taken in the extraction of the tooth, avoiding scratching the enamel or fracturing the crown. As soon as the tooth is removed place it in a mercuric chlorid solution (1 : 500 of water) at 103° F., for at least five minutes. (Why Marshall does not suggest substituting one of the hypochlorite solutions for the mercuric chlorid is not apparent. They at least would be well worth the trial.) Curet the socket, irrigate with warm mercuric chlorid, and pack with sterile gauze. Open the tooth through the crown, cleanse the root-canal thoroughly, and remove the diseased portion of the apex. Enlarge the root-canal, and give retentive shape for a gold filling; do likewise for the opening or the cavity in the crown. Irrigate the root-canal with the

mercuric chlorid solution, and replace the tooth for at least ten minutes in the solution. Fill the root-canal with chloro-percha and gutta-percha points, fill the openings of the apex and the crown with gold. Finish off carefully, as roughness of the root-apex will retard healing. Replace the tooth in the mercuric chlorid solution for at least five minutes. Remove the packing from the alveolus, replant the tooth, and cement the splint in place.

Crowned teeth are not suitable cases for this operation, because of the danger of injuring or breaking the artificial crown in extracting the tooth. This method is also contra-indicated in the case of maxillary molars with divergent roots, and occasionally mandibular molars with convergent roots. The radiograph will give this information.

Theoretically this method possesses merit. Its radicalness insures the removal of an exactly sufficient length of the tooth root, and the proper filling of the canal and closure of the root-apex. Its simplicity facilitates success without as high a degree of technical skill as is required of the operator for the usual method. Finally, this procedure appears to have a much wider range of applicability than is possessed by the more common method. Details, such as the character of antiseptic into which the tooth is immersed and the manner in which the root-canal is filled or the apical opening occluded, may be modified at the discretion of the dentist.

A priori there appears to be no justification for the present unpopularity of the method, and Marshall assures us that clinically a large majority of teeth can thereby be saved and made useful members of the dental economy. In his hands it has proved eminently successful.

[*Lancet*, London, November 17, 1917.]

A Case of Congenital Angioma of the Tongue. BY FRANK M. HUGHES.

This report is merely a brief note. The case concerns a man of twenty-six years. Examination revealed a reddish-blue growth, the size of a large marble, situated on the dorsum of the tongue, well-defined with raised edges, and smooth to the touch. On pressure the growth is reducible in size, but immediate refillment follows release of pressure. No pain has ever been caused by the growth, and

there has never been ulceration or hemorrhage from it. At the age of sixteen years the tumor had become as large as a marble, causing difficulty in mastication. This led to a condition of indigestion which became chronic.

Hughes decided not to remove the growth, as it is of the cavernous type. This would necessitate the loss of a large portion of the tongue and entail the consequent serious impairment of function of that organ.

[*Medicine and Surgery*, St. Louis, May 1917.]

Paralysis of the Facialis Caused by Salvarsan. By D. W. MONTGOMERY AND G. D. CULVER.

Salvarsan, by virtue of its arsenical content, combines a very slight degree of neurotrophism with a high degree of toxicity toward the treponema pallidum. The case here reported involved profound paralysis of both facial nerves, with a less marked implication of several other nerves and nerve systems.

In the patient, referred for anti-syphilitic treatment, there was a gradual increase in the incidence of disagreeable reactions, progressing evenly with the administration of the drug. A tentative explanation of this apparent "idiosyncrasy" is to regard these nerve affections as a repercussion on the nerves by the syphilitic virus consequent on giving salvarsan. The occurrence of such an accident as that recorded here, as it usually occurs in the early stages of syphilis and after the administration of salvarsan, would indicate some interlocking effect between the infective agent and the salvarsan.

[*Science*, December 21, 1917.]

Why Chloroform is a More Powerful and Dangerous Anesthetic than Ether. By W. E. BURGE.

It is a common observation that the amount of chloroform necessary to produce deep narcosis is less than that of ether, and that the period between slight and deep anesthesia is shorter and the lethal dose smaller with chloroform than with ether. Acidosis, resulting from the decreased oxidation in anesthesia, is much more likely to occur, and to a greater extent with chloroform than with ether.

The author adduces some evidence that makes it probable that catalase (an enzyme in

the tissues which possesses the property of liberating oxygen from hydrogen dioxide) is the enzyme in the body principally responsible for oxidation.

The decreased oxidation in anesthesia, and the probable importance of catalase in oxidation, suggested the solving of the problem in the title by determining whether catalase is decreased more quickly and more extensively during chloroform anesthesia than during ether anesthesia, parallel with the greater decrease in oxidation and the quicker and more powerful action of chloroform. Cats were used in the experiments.

Ether produced a gradual decrease in the catalase produced, while chloroform produced a very abrupt decrease during the first fifteen minutes of narcosis. "The more powerful and dangerous effect of chloroform as an anesthetic is attributed to the fact that chloroform is more potent than ether in producing a decrease in catalase, both by direct destruction of the catalase of the blood and by injuring the liver, thus decreasing the output of catalase from this organ, with resulting decrease in oxidation. The specific action of anesthetics on the nervous system, according to this hypothesis, is due to the greater solubility of the lipoids of nervous tissue, which facilitates the entrance of the narcotic into the nerve cell, and thus exposes the contained catalase more directly to the destructive action of the drug."

[*International Journal of Surgery*, December 1917.]

Significance of Dental Stigmata. By J. S. WALL.

Wall (*Arch. of Pediatrics*, October 1917) emphasizes the great importance of changes in the first permanent molar in the diagnosis of congenital syphilis. The changes in this tooth may be the only dental deformities in some instances, and are sufficiently characteristic to present no diagnostic difficulties. There is an erosion, not the erosion of wear only, but a disintegration of the grinding surface, to which this term is applied in the absence of a better one. This erosion is irregular in form: the surface of the molar for a third or a half or even the whole of its surface is pitted, excavated, and discolored. There is often a pulpy looking mass of a dirty yellow color occupying most of the face of the crown.

margined, as it were, by the line of cusps ordinarily found on the molar teeth. The tooth has been called the "honeycombed molar of hereditary syphilis." Wall also speaks of it as the "mulberry molar," likening the worm-eaten center of the cutting surface to the appearance of the tip of a mulberry.

[*New York Medical Journal*, November 10, 1917.]

Tuberculoma of the Tongue. BY CARL E. MUNGER.

The case was that of a man, age thirty years. On the dorsum of the tongue, at the junction of the middle and posterior thirds, in the median line there was a crateriform cavity. In this respect the case markedly deviated from the usually reported situation of tubercular lesions of the tongue; almost invariably these occur either on the tip or sides. This lesion being on the dorsum occupied a site on which usually a gumma is found. At the bottom of the crater there there was a marked ulceration covered with a yellowish slimy secretion, and from the central ulceration were narrow, sharply marked ulcerations radiating to the circumference of the thickened and indurated mass, whose surface color was yellowish. The slightest pressure conditioned an exquisite tenderness with much pain at every movement of the tongue. This pain was localized and not radiating when the tongue was at rest. There was present also the condition known as nigrities. If the condition were primary and strictly local, or if even accompanied by an ameliorating systemic infection, the prognosis would be favorable.

[*Journal of the National Dental Association*, September 1917.]

The Present Status of Dental Bacteriology. BY K. F. MEYER.

This is a valuable attempt to analyze and correlate the data already published on this extremely broad and refractory topic. Meyer's article would be justified, if by nothing else, at least by the wealth of reference to original publications. What is pertinent to oral bacteriology in these references is often purely incidental to the main line of thought of the investigator. This paper emphasizes the modern need of a thorough resurvey of oral

fauna and flora by the most approved current methods and standards.

The plan of Meyer's summary consists of 4 topics: (1) Bacteriology and protozoölogy of the mouth cavity; (2) microbiologic studies in relation to dental caries; (3) bacteriology of oral abscesses, chronic periosteitis and osteitis dentalis, and their importance as foci of systemic disease; (4) the etiology of pyorrhea alveolaris from the viewpoint of recent bacteriologic and protozoölogic studies.

Under the first topic the principal generalities may be stated as follows: The bacterial content of a clean mouth, on account of the neutral or slightly alkaline reaction, is aerobic and facultative anaerobic, and poor in true saprogenic organisms; in a dirty mouth the saliva is alkaline and favors the growth of anaerobes, and therefore putrefaction is evident; the oral organisms have a well-adapted idiosyncrasy for the buccal cavity, and are found outside this cavity only under pathogenic conditions, and then never in the intestines. Under pathologic conditions a shifting of the relative numerical distribution of one or of several types of bacteria of the normal mouth may occur.

The section on dental caries is essentially an exposition of Kligler's work (*Journ. Allied Dental Societies*, 1915). Meyer's paper was prepared before the appearance of Howe's studies in the *Cosmos* (October 1917, vol. lix, p. 961).

From a consideration of the data collected under the third category, Meyer concludes that the experimental proofs that the microflora of chronic foci of infection play a very important rôle in the causation of systemic diseases are not as yet entirely convincing. It is absolutely erroneous to conclude that chronic alveolar periosteitis and osteitis always represent a potential menace to the health of the human body. Predisposing factors, like pre- or co-existing disease, fatigue, etc., are vastly more important than most dentists realize. One should always suspect the presence of a pre-existing disease as an underlying factor in oral sepsis before mutilating dental operations are undertaken.

Naturally, under the fourth topic, some attention is given to the protozoölogy of pyorrhea alveolaris. Meyer believes that the final verdict will be that *Endamæba gingivalis* has no causal connection with pyorrhea, or that it

is one of many factors responsible for that condition. It is the impression of the author that probably only bacteria common to the oral cavity will be found, and that their relation to pyorrhea is the same as stated for the apical abscesses—namely, the mere presence of these bacteria means nothing, but it attains pathologic significance in this relation when associated with what is generally designated as lack of resistance (from local irritation at the gingival margin or poor nutrition and ill health).

[*Presse Médicale*, Paris, August 9, 1917.]

Cartilage Transplantation in Extensive Wounds of the Lower Jaw. BY MOR-ESTIN.

This is a report of five cases where, to make good extensive losses of tissue, transplants of costal cartilage were resorted to. The results were successful. Eight to ten months after transplantation none of the transplants showed any tendency toward resorption. Esthetically the results were gratifying, and functionally the condition was much better than it could have been without the procedure. In all cases there had been double or greatly comminuted fractures, together with widespread injuries of the soft parts.

[*Medicine and Surgery*, St. Louis, March 1917.]

Septic Parotitis. BY V. P. BLAIR.

The data from seven personal cases are correlated. From a general viewpoint there is a certain similarity between the calculous disease and septic infections of the ducts of the salivary glands and the same diseases in the bile and other excretory ducts, and it is not improbable that the different manifestations of salivary duct irritation and inflammation are as closely related to each other as are those of the bile ducts. The symptoms are essentially obstructive, with an intermittent flow of saliva or of pus and saliva. It may be that a number of cases reported as intermittent swellings, tumors, hernia, recurrent enlargement, etc., of the salivary glands are cases of actual stone irritation or obstruction. The presence of stone is not always easy to detect. In the submaxillary ducts the presence of stone is apt to dominate the picture, while in the parotid, in the absence of demonstrable stone, it is the obstruction,

and possibly the inflammation, upon which attention is focused.

Another phase of this subject is that of acute septic infection of the salivary glands, frequently described as secondary or metastatic abscess. Recent opinion has been gravitating away from this view to that which holds that most, if not all, of these cases were ascending infections of the excretory ducts. However, the seven cases described and analyzed in brief by Blair "lead one to think that possibly the older surgeons were not wrong in their metastatic conception of this particular phase of parotid infection."

The treatment is outlined, but this does not permit of abbreviation.

Two Cases Illustrating Plastic and Dental Operations. BY H. D. GILLIES.

A Few Notes on the Treatment of Gun-shot Wounds of the Mandible and Maxilla. BY W. KELSEY FRY.

[*American Journal of Surgery*, New York, December 1917.]

Healing of Lower Jawbone Defects in War Cripples. BY J. F. S. ESSER.

In an editorial in the *Lancet* of December 15, 1917, attention is focused upon the first two of the titles given above. The following remarks are of more than passing interest. In the carrying out of the procedures for the repair of the jaws and of the overlying soft parts the fundamental principle must be grasped that the surgeon and the dental surgeon should participate in the work, if the best results are to be obtained. The skilled assistance of the dental surgeon is necessary to obtain perfect replacement of the fragments; the co-operation of the two is essential. Fragments of the bone almost separated from the soft tissues may survive and assist in the union of the bone, and it is therefore of great importance not to remove unnecessarily any pieces which give the least hope of survival.

It is only the first case of Gillies' article which bears upon the work of the military dental surgeon. The case history is given in considerable detail, including the surgical procedure; six photographs facilitate its visualization. The author describes this case as a re-formation of the chin and lower lip by

double-pedicle bridge flaps and cartilage graft. The notable peculiarity of this treatment is the employment of double-pedicle bridge flaps for plastic operations. This is a broad band, left attached at the two ends, turned down into the new position, and there fixed by sutures. The flap benefits by the double blood supply, so that the risk of sloughing is markedly reduced.

Fry's paper illustrates the value of co-operation between the surgeon and the dental surgeon. It deals especially with fractures of the upper jaw. The skin of the face must be supported in the right position. "Here the art of the dental surgeon comes into play, for only by means of a prosthetic appliance can the appearance of the face be regained."

In Esser's opinion, in plastic operations a free transplantation is at best a makeshift when no way is possible to perform a plastic with a pedicle. Until the final results of the free bone transplantation are settled, Esser prefers to apply when possible a local plastic. It would be wrong to use deliberately a free bone piece without any vascular connection when a richly vascularized pedicle bone piece is available. In Esser's operations the bone piece to be placed in the defect was removed with a flap that contained all its soft covering parts (skin, muscles, and periosteum). No metal suture of the bone or wedges are used, but only three thin catgut stitches of the periosteum, and then very strong suture of the soft parts and skin. The full thickness has, in addition to the principal purpose of supplying the ideal nourishment of the bone, also the important practical consideration of cosmetic effect.

In no case treated in Esser's way did the bone piece necrose or form a sequestrum.

Studies Upon Dental Caries. BY PERCY R. HOWE AND HELEN H. GILLETTE.

The report here made is supplementary to that printed in the DENTAL COSMOS (October 1917, vol. lix, p. 961). The work was done upon children. The results of this investigation support the ideas of Klinger to the effect that in caries the character of the oral flora is changed from a streptococcal to an acid rod and thread flora.

The cultures were kept under aerobic con-

ditions. No colonies were isolated for detailed taxonomic study. The purpose was solely to gain a knowledge of comparative numbers of organisms in two types of cases, those entirely free from caries and those in which there were large numbers of decayed teeth.

The work is summarized as follows: (1) The number of organisms found in a known weight of material scraped from tooth surfaces in uncared-for mouths in which caries is present, as determined by counting plates incubated aerobically, does not vary significantly from the number of organisms found in uncared-for immune mouths. (2) Plates made from deposits obtained from carious mouths showed in general larger colonies, among them yeast forms, than those made from the deposits obtained from non-carious mouths. (3) Titrations of maltose broth cultures showed a noticeable difference in the power of acid production in the two types of cases, the factor per organism for the carious type being about five times as great as for the non-carious type.

The data from these researches show rather strikingly that as far as aerobic organisms are concerned the numbers of bacteria in the mouth are directly proportional to the amount of deposit present, regardless of the presence of caries. The difference between the flora of immune and carious mouths, as indicated by the acid production and difference in appearance of the colonies, is chiefly a qualitative difference. There is a predominance of organisms capable of producing larger quantities of acid when caries is present than when there is no caries.

[*Journal of Experimental Medicine*, Baltimore, January 1, 1917.]

The Localization of Streptococcus Viridans. BY H. K. DETWEILER AND H. B. MAITLAND.

This work was suggested by Rosenow's views that different strains of the same organism possess distinct localizing power—selective affinity. The strains employed were secured from cases of endocarditis by blood culture, from affected valves, from appendices, from tonsils, from apices of teeth, and from pyorrhea pockets. Rabbits were the experimental animals.

There were nine strains used, which had

been isolated from dental abscesses and pyorrhea. Twenty rabbits were employed. Although the largest percentage of lesions is in the heart, there is a wide variation of organs attacked. One strain from an alveolar abscess produced focal glomerular nephritis in each of three rabbits.

Taking the results of these studies *in toto*, regardless of the origin or age of the strain, we find most lesions in the myocardium, followed closely by the endocardium and joints.

The authors conclude that these experiments do not substantiate in full the theory of the power of selective action of streptococcus viridans. A few strains showed a remarkable constancy in location and type of lesion, but these strains were greatly in the minority. The location of the lesions in animals seemed to bear no relation to the origin of the organism or to the lesions produced by it in the patient from which the strain was obtained.

The Microscopic Anatomy of Chronic Periodontitis and the Pathogenesis of Dental Root-cysts. BY A. T. HENRICI AND T. B. HARTZELL.

It is the purpose of this paper to supply an adequate description of the microscopic anatomy of chronic infections of the alveolar process. The data are drawn from a review of the literature, principally German, on this subject, and from material supplied by autopsies and operations. Ground sections of jaws with the teeth and soft tissues *in situ* were prepared, and also a number of paraffin sections of gingival tissues and alveolar granulomata and cysts.

The authors note the gingival trough, and consider it analogous to the tonsillar crypts

and vermiform appendix in the sense of a locus for the accumulation of putrescible material. The earliest changes in pyorrhea occur in that portion of the subepithelial fibrous tissue lying just beneath the base of the gingival trough (or crevice). No pus cells are present, but small mononuclears are numerous, of which the vast majority are plasma cells. The only other changes noted in this initial stage are distended, new-formed, thin-walled capillaries. The inflammatory reaction is of a subacute character.

Sections of a more advanced stage of this form of periodontitis show a far more extensive infiltration of the fibrous tissues of the gum and periodontal ligament, with plasma cells and a few lymphocytes. The ulceration and suppuration are purely secondary events of pyorrhea. The pathological process remains localized to the periodontal ligament because that structure is relatively poorer in blood supply, and, what is more important, that structure is full of lymphatic channels determining the extension of the lesion. These lymphatics may also serve to explain the occurrence of lateral abscesses, which have hitherto been considered the result of hematogenous infection.

The differences between pyorrhea and apical abscess are only those of location. Both are associated with the same mouth streptococcus, invading on the one hand through the gingival trough, on the other through the root-canal. Both are inflammatory lesions of the periodontal ligament, involving in the one case primarily that portion which surrounds the neck of the tooth, and in the other primarily that which surrounds the apex. In both the processes are the same—a chronic progressive granulomatous inflammation characterized by identical cellular elements.

PERISCOPE

Cleaning Rubber Files.—Pour chloroform over the file, which causes the embedded rubber to curl up and loosen. Then take any kind of a stiff brush and remove the rubber, leaving a file that is as good as new.—L. N. ROUBERT, *Dental Review*.

Plaster Models.—Many good models are spoiled by placing the wet bite back on the model. Dry the wax with a doily or compressed air each time you take it from the mouth wet with saliva, and you will not spoil the surface of your plaster models, and your plaster will fit better.—HOMER ALMON, *Dental Review*.

Matrix for Synthetic Fillings in Adjoining Approximal Cavities.—Place a piece of soft temporary stopping between a folded celluloid strip. Put the strip between teeth with the stopping on the lingual surface, and draw both ends forward, molding the soft stopping to the lingual surface. Insert fillings, then hold back both ends.—F. G. LEVENHAGEN, *Dental Review*.

To Increase Efficiency of Local Anesthetic Solutions.—The addition of adrenalin chlorid (20 drops of the 1:1000 sol. to the ounce of local anesthetic solution) does three things: (1) Renders the operative field comparatively bloodless; (2) greatly intensifies and prolongs the anesthetic effect; (3) renders the solution much less toxic by retarding its absorption into the systemic circulation.—P. G. PUTERBAUGH, *Dental Review*.

Impression Help.—When making a maxillary impression of an edentulous case with modeling compound, it seems as though we were going to be defeated in getting it to stick. After all the details have been taken care of, very carefully heat the rim and posterior border slightly, introduce into the mouth with care, and carry it to place. Now instruct the patient to suck, as it were, on a straw immersed in syrup. This muscular and tongue effort on the part of the patient will turn the trick as nothing else can. The results are most satisfying.—*Pacific Dental Gazette*.

Patching Faulty Fillings and Crowns.—Of all things that are productive of bad results, I believe the greatest is patching. I firmly believe that 90 per cent. of all the patching of faulty fillings, bad crowns, and other defective operations are the forerunners of future trouble, many of which result in the loss of the pulp. Our filling operations should be made and can be made enduring. They should be permanent operations lasting practically a lifetime.—F. W. GETHRO, *Dental Review*.

The Paraffin Treatment of Burns.—Surg.-Col. Hurd, in the *Lancet*, June 2d, states that he has used a preparation made according to the following formula for nearly a year, with highly satisfactory results:

| | |
|-----------|----------|
| Resin, | 1 part. |
| Beeswax, | 1 part. |
| Paraffin, | 4 parts. |

Melt in a dish set in boiling water for half an hour. Apply with a metal spray to form a thick layer on the affected surface. Next cover with a very thin layer of cotton, while the wax is still hot, and then with a camel's-hair brush paint on three or four layers of the wax. After it has hardened for ten minutes, bandage.—*Amer. Journ. of Pharmacy*.

Ambrine.—This much advertised French preparation, which has been recommended so highly for burns, consists principally of hard paraffin, to which its efficacy is entirely due. Like many proprietary preparations of a secret nature, its composition is not always constant. It consists essentially of a hard paraffin combined with a small quantity of an asphalt-like body, with which combination a fatty oil has been incorporated. Undoubtedly a number of commercial paraffins on the market even without admixture of other substances will be found to answer just as well, in fact some observers have found them decidedly superior to ambrine. There is no reason why a simple paraffin wax, with a melting-point of between 44° and 48° C., should not answer every requirement for making these paraffin films.—*Journ. A. M. A.*

An Amalgam Carrier.—The best amalgam carrier is found in every dental office, if the operator knows how to use it. Any serrated amalgam plugger may be used as a carrier. The alloy is mixed as usual, not too dry, and is cut in small pieces. Touch these lightly with the pluggers you intend to use. You will find that the amalgam adheres sufficiently to allow it to be carried to the cavity. The secret is not to press too hard on the plugger or the alloy will not adhere, but instead the pressure tends to burnish it. A little practice will enable anyone to use this technique, effecting considerable saving in time and in instruments.—H. L. BROWNELL, *Pacific Dental Gazette*.

Use of Arsenic for Destroying Pulp.—My experience with arsenic as a safe destroyer of pulps was shattered many years ago, and my continued observations and study of this subject strongly confirm this previous opinion. Note that I designate this as an opinion. Nothing definite has been given to the dental profession as to whether arsenical destruction of the pulp is or is not responsible for many of the injuries to the peridental membrane at the apices of the roots. We all know what arsenic will do when it leaks through a temporary filling or when it reaches a false opening in root-canals or pulp chamber. The great destruction wrought in these cases seems to show beyond question that it is not self-limiting, and also shows very conclusively that it is an extremely dangerous drug. Many of the best men in the profession have abandoned the use of arsenic, and I firmly believe that before many years it will be eliminated by all the best-informed dental practitioners.—F. W. GETHRO, *Dental Review*.

Substitute for Platinized Gold Backing.—The purpose of using the platinized gold backing is to maintain the bluish hue at the tip of the porcelain facing, and to facilitate the flow of the solder without burning up the backing. There is, however, a serious objection to the use of the platinized gold backing, namely, platinum has a tendency to draw away from the porcelain, unless carefully overlapped, and often chips the incisal edge of the facing, due to the difference in thermal conductivity.

The use of La Croix china paint to modify the shade of porcelain is nothing new, but its use as a substitute for the platinized gold backing is original as far as the writer is concerned.

Blue china paint diluted with lavender oil is painted with a small camel's hair brush

on the lingual surface of the facing, and the pure gold backing is tried on. If the color is not correct, the china paint may be changed until it is the desired shade. The tooth can now be backed with gold in the usual way. The china paint will be sufficiently baked during the soldering process.—Y. HAYASHI, *Dental Digest*.

Indications for Gold Fillings.—The paramount issue in filling operations is to restore and preserve the tooth to its health and function for the greatest possible length of time. Gold foil, therefore, becomes so universally indicated in the ordinary cases that it becomes easier to name those cases where it is not indicated than to define those where it is. We should say gold foil is not indicated in the following cases: Where the tooth has become loosened from peridental diseases. Where extensive decay has almost completely destroyed the crown of the tooth. In a limited number of cases in the anterior teeth where cosmetics becomes the all-important consideration. In debilitated patients who are unable to be in the chair for more than a brief period of time. These patients are fortunately very few. In a very few surfaces on the molar teeth which are inaccessible. A very limited number of cases where caries have so nearly involved the dental pulp that its preservation becomes a matter of doubt. In these cases temporary plastics should be employed until such time as the destiny of the dental pulp can be more definitely prognosticated.—J. M. PRIME, *Minneapolis District Dental Journal*.

The Use of Dakin's Solution for Abscessed Teeth.—The patient was a young man, twenty-two years of age, with a chronic alveolar abscess extending from the lower first bicuspid to and including the third molar, with involvement of the alveolar process, a portion of which was necrosed, with pus burrowing down through a fistula near the angle of the jaw. It resisted all other treatment for a period of nearly two years. At the present time the abscess is closing up, discharge of pus *nil*, new granulations forming, and if nothing unforeseen develops, I am confident the case will be completely cured in about two weeks' more time.

Method of treatment. (1) I secure a fresh solution each week from a druggist (this is absolutely necessary). The druggist makes it up for me, and it is important not to get the solution too strong, as it will then produce irritation. (2) I secure a glass syringe (keep sterile) and syringe out the fistula

and all pus tracts thoroughly every day—the more and oftener you syringe the solution through the fistulas the quicker the results. (3) I give the patient a bottle of Dakin's solution to carry with him to work, and he uses it as a mouthwash, and forces it through the fistula himself several times daily, as the more it is used the better will be results. Keep sterile cotton over the opening on the outside of the jaw.—P. L. MARSHALL, *Dental Summary*.

Uselessness of Vaccines and Emetin in the Treatment of Pyorrhea.—Regarding the bacteriology of pyorrhea, it can be said that at present there is no evidence that it is caused by a specific bacterium; on the contrary, there is plenty of evidence that it is not. Studies of the bacterial flora of pyorrhea have shown that it does not differ qualitatively from that of the normal mouth. As might be expected there is a great quantitative difference inasmuch as pyorrheal conditions are conducive to bacterial growth. Investigations carried on at the Research Laboratories of the New York Health Department through my initiative have proved this beyond question. They showed, moreover, the extraordinary complexity of the bacterial flora of pyorrheal lesions; spirochetes and fusiform bacilli preponderated. No less than fifteen different strains of the latter were isolated and carefully studied, and nothing distinctive of pyorrhea was found. Cocci of every known strain were found as were many other morphological types. Comparisons with cultures taken from normal mouths were made only to find that the same organisms were to be met with, but in greatly reduced number, showing the difference to be purely a quantitative one. The use, therefore, of vaccines in the treatment of pyorrhea is illogical in the extreme. The same may be said of emetin. While it is an efficient amoebicide, and will destroy amoebæ, which are always present in pyorrheal lesions (as they are in every filthy mouth), it has no curative effect.—A. H. MERRITT, *New Jersey Dental Journal*.

Gold Foil Fillings for Restoring Tooth Form.—Cohesive gold foil is the king of filling materials, and with it the very valuable tooth forms may be wonderfully well reproduced. In the restoration of the normal occlusal forms this material works most beautifully. The grooves, pits, incline planes, and cusps are easily reproduced with small pellets, using the various plugger points as the operation is built up and finished. No more beautiful forms are possible in inlays or

amalgam than may be made with this unique filling material. The other surfaces, so vital to physiological function, are likewise as easily and positively reproduced.

It is not the purpose of the writer to condemn the porcelain or gold inlay. Both the direct and indirect methods hold many possibilities. We should dislike to part with them in our practice. We are not in any sense condemning the use of amalgam. We consider it a valuable filling material, and would not want to practice without it. This is what we do wish to emphasize: That gold foil is not a "lost art," but when properly understood will rapidly come to its own. Already the disgraceful results of easy slipshod methods are becoming apparent. Interest everywhere is becoming aroused for safer, saner, and surer methods. Cohesive gold foil offers a surer and safer method in a wide range of cavities. Gold-foil technique should be thoroughly mastered in our colleges, demonstrated in our societies, taught in our study clubs, and more generally employed in our offices.—J. M. PRIME, *Minneapolis District Dental Journal*.

Treatment of Active Hyperemia of the Pulp.—The treatment of this condition consists in protecting the tooth from the irritant which caused the disease. If a cavity exists which is causing the trouble an anodyne remedy is indicated. One treatment with phenol compound, or other remedies possessing similar properties, should cure a case of active hyperemia due to caries of the tooth. At the second sitting, if the case has a favorable history, the rubber dam should be adjusted and the dressing and carious dentin removed, after which a base of cement may be inserted, the cavity prepared, and the tooth filled. In those cases where the cavity is deep and encroaches upon the pulp, and where the removal of the softened dentin practically exposes the organ, it is necessary, in order to save the pulp, to protect it by the use of some antiseptic paste. Here I use thymolized calcium phosphate as the powder and oil of cloves as the liquid to make such a paste. Just a little aristol or euclophen—iodin compounds—is added to the paste after it is mixed to the proper consistence, which should be like softened gelatin. In cases of actual exposure, the pulp should be destroyed and removed, unless some exceptional reason obtains for preserving the life and functioning powers of the organ; and even in cases of near exposure, one must be careful that the pulp is acutely alive and normal, for in many cases it simply dies without the manifestation

of the usual pathologic symptoms. Such stimuli as heat, cold, and electricity may be used to test the acuteness of the vitality of the pulp. Should it fail to respond to these tests, or should it ache severely without ceasing momentarily, it had better be removed.—J. P. BUCKLEY, *Dental Review*.

Nerve Blocking.—The advantages of nerve blocking are numerous, but the following will serve as suggestions of some of the most important:

(1) The duration may be changed by varying the amount of the vaso-constricting agent. The long duration is of great value to the operator for the removal of impacted third molars, reducing fractures, treating the antrum, root amputation, removal of tumors, cavity preparation, removal of pulps, and many other similar operations which may come within the observation and practice of the oral surgeon or general practitioner.

(2) Large or small areas may be anesthetized, depending upon the nerve branch or branches blocked.

(3) Anesthesia is secured in infected or inflamed areas by blocking the nerve branch at a point some distance from the operative field, and in the healthy tissue.

(4) Nerve-blocking injections, when skillfully made, are without pain, for the reason that the needle is inserted and the solution injected in the mucous membrane and in loose connective tissue.

(5) One or two insertions of the needle will block the operative field, depending, however, upon the nature of the operation and the area to be blocked.

(6) Co-operation of the patient. It is well known that this is of material advantage to the operator, because he can operate with ease and complete the operation on the patient with a minimum amount of laceration, and without the inspiration of blood and mucus.—ARTHUR E. SMITH, *Minneapolis District Dental Journal*.

Matrices for Amalgam.—For amalgam we wish a matrix which will conform closely to the general outline of the tooth, which is thin, yet strong and pliable, and wide enough to extend beyond the gingival and occlusal margins of the cavity; and finally, one which can be quickly adjusted and easily removed with the minimum of danger to the filling.

The materials used in this clinic, Angle's C and H band material, particularly C, will be found very useful in the majority of cases requiring matrices.

Having secured the necessary separation and prepared the cavity (Black's prepara-

tion preferred), a piece of band material is cut which will be long enough to extend halfway around the tooth—entirely around if preferred. Hold this in position on the tooth and mark the contact point. Contour the band at this point. Make two ears on the gingival margin of the band, one buccally and one lingually, and through these ears and around the matrix pass a piece of dental floss. Place the matrix on the tooth and ligate tightly, passing the ligature around twice if necessary, and tying with a surgeon's knot. Burnish the matrix around the edges of the cavity to assure close adaptation. Cotton may be packed between the teeth to assist in resisting the pressure while inserting the filling. Having inserted the filling, cut the ligature holding the matrix, grasp one end of the matrix in a pair of pliers, and gently pull down and out. The filling will have a smooth surface and can be easily and quickly trimmed, contoured, and polished.—L. C. BROWNTON, *Journ. Cal. State Dental Association*.

Advantages of Phenol-Sulfonic Acid in the Treatment of Pulpless Teeth.—The chemical action of sulfuric acid and phenol-sulfonic acid for the use under consideration is practically the same; and they will be discussed here conjointly. Personally, I prefer phenol-sulfonic acid. Its consistence is thick and syrupy in the 80 per cent. strength which is recommended; thus a drop will adhere to the end of the broach or other applicator, permitting it to be carried even into the canals of upper teeth without difficulty. The acid does not materially affect a broach, and if any of it accidentally gets on the enamel of the crown of the tooth and is not noticed for a time, it does not decalcify and whiten the spot to the extent that sulfuric acid would do. It might be supposed by those who have not used phenol-sulfonic acid that, possessing the above-mentioned advantages over plain sulfuric acid, it would be less effective in the canal. I have not found this to be the case. The agent has one possible disadvantage. In using either of these acids, after they have been introduced into the canal for a time and the walls thereof filed with a suitable broach, they should be neutralized with a solution of sodium bicarbonate. In the case of sulfuric acid the salt formed as a result of the reaction is sodium sulfate, a freely soluble salt. With phenol-sulfonic acid the salt formed is sodium phenol-sulfonate, which is not as soluble as sodium sulfate. I can conceive how it might be possible in a very fine canal to temporarily block it with the salt

formed. An excess of water would readily dissolve the salt, or by using a solution of sodium bicarbonate of not more than 10 per cent. strength the salt would be dissolved as soon as formed by the reaction. This is a thing which probably would never occur in practice; but I mention it as a possible disadvantage.—J. P. BUCKLEY, *Dental Review*.

Muscle Trimming.—An easy way of performing muscle trimming is as follows: Warm the left buccal margin of the impression material over the flame, dip into hot water, and lift up the left cheek so as not to distort the soft margins while inserting the impression tray into the mouth. Instruct the patient to close the mouth; this will bring the buccinator muscle to the middle position. Then ask the patient to open the mouth; this will bring the muscle to the posterior position. Instruct the patient in the whistling and laughing motions, which will muscle-trim in the anterior position, and immediately massage over the cheek. Cool the tray with a spray of cold water to hasten the hardening of the compound. Then warm the buccal margin on the right side of the impression, and repeat as on the left side. Next warm the labial margin, ask the patient to perform the whistling motion, and then massage over the lip.

The next step is to have the tuberosities well covered. If any part of the impression at these points is deficient, add compound, and use the finger to help carry the compound over the tuberosities.

The next step is to adapt the impression to the soft tissues of the palate. These tissues should be in a relaxed position when the adjustment is made. This is accomplished by adding compound over the entire area occupied by these tissues. Pass this part of the surface over a gas flame, dip into hot water, insert in the mouth, and instruct the patient to swallow two or three times. During the act of swallowing, the tongue is automatically carried to the roof of the mouth, and tends to drive the softened compound into firm contact with the soft tissues. Pass the right forefinger across the heel of the tray, and with firm pressure help the compound to adapt itself firmly to the soft palate and tuberosities. Immediately have the patient close the mouth and swallow.

According to Dr. Greene an upper plate should fit snugly, but should not be uncomfortably tight. A plate which can be rotated slightly from side to side without breaking suction is preferable to one very firmly fixed in the mouth.—J. ADER, *American Dentist*.

Dentistry Twenty Years Ago and Today.

TWENTY YEARS AGO.

Dentists were using cataphoresis for alleviating pain.

Somnoform was unknown.

"Iron-pin" teeth made their appearance.

Porcelain workers were coming into their own.

Orthodontist and exodontist were words used to scare children.

Focal infection was not thought of.

Platinum sold at \$11 per ounce.

Prophylaxis was a word only few could even pronounce.

Gas was administered through a drum containing water to "purify it."

All the dental laboratories might have been counted on the fingers of two hands.

X-rays were only dreams.

TODAY.

Novocain with conductive anesthesia is the remedy to alleviate pain.

"Palladium pins" in bridge teeth are universally used.

Porcelain workers are beginning to sit up and take notice again.

Every city of 50,000 has its specialist in regulating and extracting.

The danger of focal infection is now so great that thousands of words have been written on the subject, and discussions galore started.

Patients are being taught how to massage their gums, how to brush their teeth, and the value of prophylaxis is generally understood.

Nitrous oxid and oxygen mixed in a highly scientific manner is used freely as an anesthetic, with the best results.

X-rays play an important part in every modern dental office. It's the difference between "know" and "guess."

Over two hundred laboratories now seek to serve the dental profession.—*Nebraska Dental Journal*.

Plaster Impressions of "Partial" Cases.

—In an edentulous jaw, any overhanging or moderately undercut parts will in most cases yield sufficiently to permit withdrawal of the impression without fracturing it. In a tooth-bearing jaw, some of the overhanging surfaces are rigid or non-yielding, so that the impression plaster must fracture in one or more places before removal. This difference in the conditions will affect the impression technique in several ways. The attempt to effect simultaneous removal of tray and impression will seldom produce a good impression; even in the case of a young child's mouth, an un-

fractured impression would be incomplete for study purposes. In many tooth-bearing cases an unfractured removal would be impossible.

Leaving the impression *in situ*, the tray is detached and removed, first freeing it, if needful, from any restraining portions of plaster that may overhang its external border. The labial and buccal walls of the impression are then broken away, in as few pieces as may be practicable. This will be difficult when a very roomy and loosely-adapted tray has been used, and relatively easy when, with a well-adapted tray, the line of fracture runs across a thinner layer of plaster. But even with a suitable tray, it is obvious that if it is not pressed properly

home into position the layer of plaster along its floor will be unnecessarily thick, and difficult to break.

In a deep gap between leaning teeth the impression plaster will of necessity be thick and difficult to break; it may then have to be cut or notched with a knife to facilitate fracture and removal. Anticipating this difficulty it is better to provide beforehand for its easier solution. That may be done by first securely attaching to the floor of the tray a ridge of wax running mesio-distally along the site of the gap, so that when the tray is removed we have a notch ready formed in the plaster, and sufficiently deep to make fracture easy.—D. M. SHAW, *Dental Record*.

OBITUARY

Dr. Reuben Hollenback.

DIED, Thursday, December 27, 1917, at his home, Shamokin, Pa., from peritonitis. REUBEN HOLLENBACK, D.D.S., in his seventy-seventh year.

Dr. Hollenback was born September 1, 1841, in Lower Augusta township, Pennsylvania, the son of Daniel and Elizabeth (Sherry) Hollenback. He obtained his early education in the public schools of Lower Augusta township, and followed the occupations of farming and school-teaching until the year 1864, when he removed to Shamokin, Pa., where he also taught school for several years.

In 1868 Dr. Hollenback began the study of dentistry under the tutorship of Dr. B. F. Van Buskirk of Selinsgrove, Pa. He later entered the Pennsylvania Dental College at Philadelphia, from which he was graduated in 1877. After graduation, Dr. Hollenback returned to Shamokin, and began the practice of dentistry, which he continued until the time of the illness which resulted in his death. He was a member of the Pennsylvania State Dental Society and the Susquehanna Dental Association.

Dr. Hollenback was not only a capable and progressive dentist, but an active and prominent figure in the affairs of his community, which he served for many years as councilman. In this position, by his conscientious

attention to detail, he proved himself a most capable public servant. He was also active in religious affairs, having been born and reared in the faith of the Reformed Church, in which he was a regular and faithful attendant at divine worship, as well as a teacher in the Sunday school.

Dr. Hollenback was twice married. His first wife was Miss Dorothy Sober, who died in October 1887, leaving him three children, two of whom, Dr. Hudson Hollenback, a practicing dentist of Mount Carmel, and William S. Hollenback, a merchant of Reading, Pa., survive him.

In December 1888 Dr. Hollenback was married for the second time to Miss Savilla Fidler of Shamokin, who, with two children, also survives him.

The funeral services were held on Monday, December 31st, at his late home, and interment occurred in the family plot at Shamokin cemetery.

Dr. Burford L. Shobe.

DIED, October 14, 1917, at his home in Tulsa, Oklahoma, in his fifty-fifth year, BURFORD L. SHOBE, D.D.S.

Dr. Shobe was born in Smith's Grove, Warren County, Ky., February 6, 1863. At the age of eighteen he moved with the family to Wellington, Kans., at which place he took

up the study of dentistry with Dr. Garnette, and was later graduated from the Ohio Dental College. After graduation he located in Garden City, Kans., where he practiced twenty-four years. From Garden City he went to Kansas City, Mo., and entered into the dental supply business. In 1908 he disposed of his interest in the business and moved to Bartlesville, Okla., to resume the practice of dentistry. Five years later he located in Tulsa, Okla., where he was practicing at the time of his death. He is survived by his wife.

Dr. Fred M. Smith.

DIED, at his home in Chester, Pa., on Friday, January 11, 1918, in his sixty-fourth year, from dilatation of the heart, FRED M. SMITH, D.D.S.

Dr. Smith was born July 22, 1854, in New York State, near Rochester, where he obtained

his early education. He began the study of dentistry in 1878, at the Philadelphia Dental College, from which institution he was graduated in 1880. In the same year he began the practice of his profession in Chester, associating himself with the late Dr. Thaddeus Monroe.

Dr. Smith was quite active in dental and civic affairs, being a member of the Pennsylvania State Dental Society, the National Dental Association, as well as of the County Dental Society. He was prominent in Masonic circles, being a member of the Chester Lodge, the Chester Commandery, and had received the thirty-third Masonic degree.

Dr. Smith was married in 1894 to Miss Marietta F. Cloud of Chester, who with his mother survives him.

The funeral services were held Tuesday, January 15th, at his late home, and interment took place in the Chester Rural Cemetery.

Death of Dr. John W. David.

WE regret to announce the death of Dr. J. W. DAVID, of Corsicana, Texas, December 29, 1917. A full obituary notice of Dr. David will appear in our next issue.—Ed.

DENTAL LEGISLATION

Maine Dental Law Providing for Dental Hygienists.

AN ACT

ALLOWING DENTISTS TO EMPLOY WOMEN ASSISTANTS WHO SHALL BE KNOWN AS DENTAL HYGIENISTS.

SECTION 1. Any registered or licensed dentist may employ women assistants who shall be known as dental hygienists. Such dental hygienists may remove lime deposits, accretions, and stains from the exposed surfaces of the teeth and directly beneath the free margin of the gum, but shall not perform any other operation on the teeth or mouth or on any diseased tissues of the month. They may operate in the office of any registered or licensed dentist or in any public or private institution under the general supervision of a registered or licensed dentist. The State Board of Dental Examiners may revoke the license of any registered or licensed dentist who shall permit any dental hygienists operating under his supervision to perform any operation other than that permitted under the provisions of this section.

SEC. 2. No person shall enter practice as a dental hygienist in this state until she has passed an examination given her by the Board of Dental Examiners of this state, or a subcommittee of said board which it may appoint, under such rules and regulations as it may deem fit and proper to formulate. The fee for said examination shall be ten dollars, and any applicant failing to pass said examination shall be entitled to one additional examination without further cost. The fee for each re-examination after the first shall be five dollars. The said Board of Dental Examiners shall issue certificates of ability to practice as dental hygienists in this state to those who have passed said examination; *provided*, however, that no person shall be entitled to such certificate unless she shall be eighteen years of age, of good moral char-

acter, and shall have had an education equivalent to that attained by one year's attendance upon the class A high schools of this state as defined by section seventy-three of chapter sixteen of the Revised Statutes, and unless she is a graduate of a reputable training-school for dental hygienists or shall present a sworn statement by a dentist licensed to practice dentistry in this state that she has completed a course of at least six months' training as a dental hygienist under him.

SEC. 3. The Board of Dental Examiners of this state may at its discretion without the examination as herein above provided, issue its certificate to any applicant therefor who shall furnish proof satisfactory to said board that she has been duly licensed to practice as a dental hygienist in another state after full compliance with the requirements of its dental laws: *provided*, however, that her professional education shall not be less than that required in this state. Every certificate so given shall state upon its face the grounds upon which it is granted, and the applicant may be required to furnish her proof upon affidavit. The fee for such certificate shall be ten dollars.

SEC. 4. All acts and parts of acts inconsistent herewith are hereby repealed.

Approved April 7, 1917.

THIS bill, in accordance with the law, became operative ninety days after the adjournment of the Legislature on July 7th, but the Attorney-general of Maine gave it as his opinion that no examinations under this act could be held until six months after July 7th, *i.e.* after January 7, 1918, because the act provides six months' training of the hygienist, and he ruled that this must come after July 7th.

ARMY AND NAVY DENTAL NEWS

THE NAVY DENTAL RESERVE CORPS.

Circular issued April 1, 1917, by the Surgeon-general, U. S. Navy

FOR THE INFORMATION OF

Persons Desiring to Enroll in the United States Naval Reserve Force as Dental Officers.

A CANDIDATE for enrollment as a dental officer is first examined for enrollment in the provisional grade of dental surgeon, rank of lieutenant (junior grade), United States Naval Reserve Force. Afterward, if his enrollment is accomplished, should he so desire he makes request for active duty for confirmation in grade, and after the completion of a minimum period of three months' active service (at sea) he is again examined, and if found qualified is recommended for a commission as a dental surgeon, United States Naval Reserve Force.

Legislation establishing the United States Naval Reserve Force contains in substance matter referable to the grade of dental surgeon as follows:

A member must be a citizen of the United States, except as noted below with reference to the Naval Auxiliary Reserve.

A member obligates himself, and may be ordered to serve in the navy throughout a war or during the existence of a national emergency declared by the President, should either arise during his term of enrollment.

A member enrolls or re-enrolls for a term of four years.

In time of peace, and when no national emergency exists, a member may be discharged upon his own request, upon reimbursing the Government for any clothing gratuity that may have been furnished during his current enrollment.

A member is required to take the oath of allegiance to the United States.

A member is given a provisional grade (dental surgeon) upon first enrollment in accordance with his qualifications determined by examination.

A member after enrolling may, in time of peace, upon his own request, be assigned active duty in the navy for such periods of instruction and training as may enable him to qualify for and be confirmed in grade.

For confirmation in grade a member must serve the minimum amount of active service required (three months), and must qualify by examination under regulations prescribed by the Secretary of the Navy.

The minimum active service required for maintaining the efficiency of a member (Naval Coast Defense Reserve) is three months during each term of enrollment. This active service may be in one period or in periods of not less than three weeks each year.

No person shall be appointed or commissioned an officer in any rank in any class of the United States Naval Reserve Force, or promoted to a higher rank therein, unless he shall have been examined and recommended for such appointment, commission, or promotion by a board of three naval officers not below the rank of lieutenant commander, nor until he shall have been found physically qualified by a board of medical officers to perform the duties required in time of war, except that former officers and midshipmen of the navy who shall have left the service under honorable conditions and who shall have enrolled in the United States Naval Reserve

Force may be appointed in the grade and rank last held by them without examination other than the physical examinations herein prescribed.

A member receives retainer pay of \$12 per annum while enrolled in a provisional grade, provided he makes such reports concerning his movements and occupation as may be required by the Secretary of the Navy. After confirmation in grade his annual retainer pay is two months' base pay of the corresponding rank in the navy. Retainer pay is in addition to any pay to which a member may be entitled by reason of active service. As noted below, members of the Volunteer Naval Reserve do not receive any retainer pay.

A member who re-enrolls for a term of four years within four months of expiration of last complete enrollment, and who has performed the minimum amount of active service required during the preceding term of enrollment, for each re-enrollment receives an increase of 25 per cent. of his base retainer pay. A member who completes twenty years of service, and who has performed the minimum amount of active service each term of enrollment, on his own application will be retired with rank held, with a cash gratuity equal to the total amount of his retainer pay during his last term of enrollment.

A member may accept employment in any branch of the public service, *except* as an officer or enlisted man in any branch of the military service of the United States or any State thereof.

A member is subject to the laws, regulations, and orders for the government of the regular navy only during such time as he may by law be required to serve in the navy in accordance with his obligation, and when on active service at his own request, and when employed in authorized travel to and from such active service in the navy.

A distinctive badge or button will be issued, to be worn only by members of the United States Naval Reserve Force. A penalty is assigned where unauthorized persons wear or use this emblem.

A member actively employed receives the same pay and allowances, gratuities, and other emoluments as an officer of the naval service on active duty of corresponding rank and of the same length of service. When not actively employed a member is not entitled to pay, bounty, gratuity, or pension, except as expressly provided by the provisions of the act.

When first reporting for active service for training during each period of enrollment officers are credited with a clothing allowance

of \$50, except as noted below with reference to the Volunteer Naval Reserve. In time of war or national emergency he is credited with \$150, less the amount previously credited, if any, during the current enrollment.

Officers in the United States Naval Reserve Force rank with but after officers of corresponding rank in the navy. Officers are commissioned by the President.

Enrollment.

* * * * *

A candidate for enrollment as above must be between twenty-one and forty-four years of age and a citizen of the United States. He must be a graduate of a reputable dental or medical school, legally authorized to confer the degree of doctor of dental surgery.

Application for enrollment must be made in the handwriting of the applicant according to the following form:

FORM OF APPLICATION.

(This form is not to be filled in here, but copied on a separate sheet in the handwriting of the applicant.)

.....
(Residence.)
.....191 .

SIR: I request permission to be examined for enrollment in the provisional grade of dental surgeon, rank of lieutenant, junior grade, Naval Coast Defense Reserve, Class 4, United States Naval Reserve Force.*

I was born at....., and was..... years of age on theday of, 191 ; graduated from.....dental (medical) school in 19 , and am licensed to practice dentistry in the State of..... I am a citizen of the United States, residing in....., county of....., in the State of.....

I forward herewith letters testifying to my moral character, habits, citizenship, preliminary education, dental education, society membership, license to practice dentistry, and professional qualifications.

Very respectfully,

.....
(Name in full written legibly.)

CHIEF OF THE BUREAU OF MEDICINE AND SURGERY,
Navy Department, Washington, D. C.

* When directed, the applicant should substitute the words "Volunteer Naval Reserve for duty in the Naval Coast Defense Reserve, Class 4, United States Naval Reserve Force" for the words "Naval Coast Defense Reserve, Class 4, United States Naval Reserve Force."

The above application must be accompanied by the following certificates:

(a) Letters or certificates from two or more persons of good repute, testifying from personal knowledge to good habits and moral character.

(b) A certificate or statement from some person of good repute that the applicant is a citizen of the United States. In case the applicant is a naturalized citizen of the United States his naturalization papers, or other satisfactory evidence of citizenship, must be submitted.

(c) Certificate of preliminary education. The candidate must submit a certificate of graduation from an accepted high school or an acceptable equivalent.

(d) Certificate of dental education. This certificate should give the name of the school and the date of graduation.

(e) A certificate from the president or secretary of a state or local dental society to the effect that the applicant is a member in good standing.

(f) A certificate of license to practice dentistry.

(g) If the candidate has had hospital service or special educational or professional advantages, certificates to this effect, signed by the proper authorities, should also be forwarded.

The applicant will save unnecessary correspondence if he will make sure when submitting his application that the qualifications enumerated above are clearly and plainly described in his letters or certificates.

After passing upon the credentials of the candidate, the Bureau of Medicine and Surgery will issue a permit to the candidate, effective for a stated period, to appear before medical and dental examiners designated by the bureau via the commandant or commanding officer, for his provisional physical and professional examination. The permit will direct the candidate to communicate with the senior examiner as to the date and place of examination. An effort will be made to select the place of examination as near as possible to the place of residence of the candidate.

The Examination.

When a candidate presents himself for examination on the date fixed by the senior examiner, he must bring with him the testimonials as to character, habits, citizenship, preliminary education, dental education, membership in a state or local dental society,

license, and letters describing professional qualifications, those forwarded with his application being returned to him for the purpose.

The examination is conducted in the following order: I. Physical. II. Professional.

I. PHYSICAL EXAMINATION.

(See separate circular regarding physical requirements inclosed.)

The physical examination is thorough, and the candidate is required to certify that he is free from all mental, physical, and constitutional defects.

Acuteness of vision, 12/20 for each eye, unaided by glasses, but capable of correction by aid of lenses to 20/20, is obligatory. Color perception must be normal and the teeth good.

If the candidate is found to be physically disqualified the examination is concluded; but, in the case of a candidate otherwise desirable, the examiners may recommend that minor disqualifications or departures from standard be waived, and proceed with the professional examination, subject to final approval by the department. If found to be physically qualified, his examination is continued as follows:

II. PROFESSIONAL EXAMINATION.

1. Letter to the board describing in detail his general and professional education.

2. Examination of diplomas, certificates of state boards, certificates of membership in dental societies, letters, and such other recommendations or certificates bearing upon the professional qualifications of the applicant as he may desire to submit.

3. Oral examination in the several usual subjects in a standard dental course; to include operative dentistry, prosthetic dentistry, and oral hygiene.

A practical examination in operative and prosthetic dentistry may be required.

This examination will be sufficiently comprehensive to determine whether the candidate is qualified to practice dentistry under the usual service conditions.

Due credit will be given for knowledge and experience in the case of candidates who have specialized in certain branches, and the examination may be modified accordingly. A successful candidate, upon the completion of his examination, will be notified by the president of the board that he has been found qualified. The board will assign an average mark based on a passing mark of 75 per cent.

With the consent of the examiners, a candidate may withdraw at any period from fur-

ther examination and may at a future time present himself for re-examination, provided that such examination is not delayed until after the date that his permit would expire.

No allowance will be made for the expenses of persons appearing for examination.

If the medical and dental examiners find the candidate duly qualified physically and professionally for enrollment in the provisional grade of dental surgeon, rank of lieutenant, junior grade, Naval Coast Defense Reserve, Class 4, United States Naval Reserve Force; or Volunteer Naval Reserve for duty in the Naval Coast Defense Reserve, Class 4, United States Naval Reserve Force; they will immediately forward a report and recommendation to this effect direct to the Bureau of Medicine and Surgery, together with the certificate of the candidate as to his physical condition, the personal history and physical data form, and the letter of the candidate to the examiners. A report and recommendation will also be made when a candidate is found disqualified.

After approving the record of examination and the recommendation of the examiners in the case of a qualified candidate, the Bureau of Medicine and Surgery will recommend to the Bureau of Navigation the provisional enrollment of the candidate in the United States Naval Reserve Force.

Upon accepting the certificate of enrollment the candidate is required to take the oath of allegiance and to certify, on oath, as to his citizenship and age.

A member of the United States Naval Reserve Force may transfer to or from the Volunteer Naval Reserve upon approval by the Bureau of Navigation of his request to this effect.

* * * *

Pay and Allowances.

Dental Officers of the Naval Reserve Force when on active duty receive the pay and allowances of officers of like rank in the navy, the pay of lieutenant (junior grade) being \$2000 annually, or \$166.66 per month. An increase of 10 per cent. is added when serving at sea or on a foreign station. When on active duty on shore they are also furnished with quarters either in kind, three rooms, or commutation at the rate of \$12 per month per room allowed, and fuel and light, or an allowance therefor, are also furnished. When traveling under orders mileage is allowed at the rate of 8 cents per mile.

Dental officers enrolled in the United States Naval Reserve Force shall be appointed in time of peace not to exceed fifty in number.

For further information address the Surgeon-general, U. S. Navy, Navy Department, Washington, D. C.

Dental Treatment in the English Army.

By Capt. W. L. CROCKER, R.A.M.C., Hove, Eng.

(Reprinted from the *Journal of the Royal Army Medical Corps.*)

AN important aspect of army dental work does not appear to have received the attention it merits. I refer to the modifications of dental treatment that have been the result of experience in the treatment of troops.

All of us, commissioned dental officers and civilian dental surgeons, commenced our work with the idea that every savable tooth should be filled, and every unsavable tooth should be extracted and, if necessary, dentures provided to fill the gaps. Some of us even went so far as to extract on a large scale for the cure of pyorrhea.

At the present time the views of the authorities are clearly laid down, and it is for us to give effect to the instructions in the most intelligent manner we can. The latest instruction points out that stumps are often

more useful than dentures. It is stated that only efficient mastication is necessary, but it is not always easy to decide what constitutes efficient mastication. Further, we are told to pay more attention to the cleaning of mouths, but according to our preconceived ideas this constitutes extraction in preparation for dentures in most cases.

My experience has led me to adopt certain principles which I believe are in accordance with the views of the authorities and which may be of interest.

(1) *Scalings.* Every scaling is necessary. The reason is not so much a surgical as a military one. The soldier is taught habits of cleanliness, and the cleaning of his teeth is one of the most important. He cannot keep his teeth clean if they require scaling, and there-

fore, apart from the surgical aspect, scaling is a necessity. There is reason to believe that scaling is appreciated by the majority, and it is the foundation of regular habits of cleanliness.

(2) *Fillings.* It soon becomes clear in treating soldiers that to fill every savable tooth is unnecessary, even if it were possible. When, however, the soldier has lost so many teeth that further extraction would render dentures necessary, any cavities that exist must be filled.

Sometimes it is possible to select one side of a man's mouth for filling, and give the soldier a comfortable masticating surface: the other side can then be entirely neglected. It is very important to fill teeth supporting dentures. I have been impressed by the large number of teeth in which the caries has become naturally arrested, and advantage of this tendency can often be taken.

(3) *Extraction.* In examining, it becomes apparent that there are large numbers of useless stumps whose removal would still leave efficient mastication. A feeling of dissatisfaction is created in the mind of the soldier by the extraction of such stumps, because he thinks he is entitled to have them replaced. It should always be explained, therefore, that substitutes will not be allowed, and the soldier will usually prefer to leave the stumps until they give him trouble. In cases, however, where there are symptoms of general ill health probably caused by oral sepsis, such extraction has to be insisted upon.

Extraction in preparation for dentures forms the greater part of our operative work, and is by far the most important part of our work. It is to be regretted that in so large a proportion of cases the teeth are beyond saving. Such, however, is the case, and we are faced with the problem as to whether the teeth must be extracted and dentures provided, or the soldier allowed to continue using his stumps for mastication. It is impossible to lay down a sweeping rule, and each case has to be judged on its merits.

The following points concerning dentures have to be considered. I am aware that they are not in accordance with text-book teaching, but from a military point of view I am convinced of their soundness:

(a) As a mechanical contrivance dentures are inferior to stumps, provided the stumps are not tender.

(b) From a surgical point of view dentures are a greater abomination than stumps, under active service conditions, unless there is some

incentive for the soldier to keep his dentures clean. It must be borne in mind that the soldier under fire lives in a state of tension, and his daily habit of cleaning his teeth tends to be neglected. Even officers neglect their teeth-cleaning, sometimes because clean water is scarce, but generally because they forget.

If we could follow the men for whom we have provided dentures out to the front a fortnight later, and could examine their dentures, in a large percentage of cases we should find the dentures in a far more septic condition than the original stumps. Even in the training camps at home, my experience shows that the men with dirty tongues and offensive breath are the men who wear dentures, while the men with stumps have clean tongues and breath. The soldiers who take care of their dentures at the front are invariably those who have reason to be grateful for the provision on account of improved health and greater comfort.

(c) Dentures are liable to be broken or lost, the gums may shrink and the dentures become loose, and the loss of a tooth supporting a denture may render the denture useless. In any of these circumstances, a visit to a base at the public expense is necessary, besides the loss of a fighting unit for a week or two.

The vast majority of men whose teeth are mostly stumps are enjoying good health. A parade of a large number of such men leaves no doubt. In civil life under the social conditions that existed before the war, their daily occupations tended to lower their resistance. When they enter the army their habits of life become regular; in most cases they are better clothed and fed than ever before, and they are put through a graduated course of training and exercise especially designed to make them fit. Surely, if they enjoyed good health before, they will do so now. Their dental condition was neglected before, and now if the mouths are scaled and cleaned, the habit of the toothbrush acquired, and essential teeth carefully filled, nothing more is needed to insure continued health in the vast majority of cases.

There remains, however, a proportion of cases whose dental condition is responsible for ill health in one form or another. Such men are classed as category "A," which does not mean they are physically fit for the front at the time of enlistment, but that they are likely to become fit as a result of the training. Some of them become fit in spite of the dental condition, but for most of them dental treatment is absolutely necessary.

It is therefore essential that the dental surgeon should see the men when they are first drafted to the training center, so that, in consultation with the medical officer, the history of each case can be gone through where the teeth are mostly stumps, and it can be decided as to what extent the condition has affected the general health, whether the training is likely to eliminate the symptoms, or whether extraction in preparation for dentures would not only be genuinely appreciated by the soldier himself, but would be the determining factor as to whether or not he would ultimately become fit for the front.

Extraction vs. Preservation of Teeth in the English Army.

[THE following letter to the editor of the *British Dental Journal* is reprinted from the Correspondence department of that journal.—ED.]

Sir,—As a dental surgeon, with two years' experience of work among the troops near the front, I was delighted to read Captain Finn's paper in your issue of January 15th. His remarks on the provision of dentures express

my views exactly. There is far too much eagerness to "clear out" roots and decayed teeth, thereby putting the man *hors de combat* for a considerable time. A large portion of these men subsequently fitted with dentures eventually carry the latter in their pockets or haversacks, where they get broken or lost, or break them on the first biscuit they attempt to eat. My plan has always been to preserve every scrap of tooth substance possible. Many a mouth, which at first view looks quite hopeless, when cleaned and the soft and decayed dentin cleared away, if the remaining cavities and roots are rapidly filled or capped with cement, after sterilization, can be rendered quite serviceable, and the man can "carry on" in comfort for several months. Half a dozen roots when opposed by teeth in the opposite jaw are of far more value out here than when replaced by the most perfectly fitting denture. In my opinion, it is waste of time and material to fit up middle-aged men with dentures who have not previously worn them, and who are proceeding to the front.

C. L. MACKANESS, *Capt. Dent. Surgeon,*
Att. R. A. M. C.

Army Dental Corps: Information as to Examinations.

TWO HUNDRED AND FIFTY VACANCIES TO BE FILLED.

(1) THE Surgeon-general of the Army announces that there are, at the present time, approximately 250 vacancies in the Dental Corps, and that examination for the appointment of dental surgeons will be held at various points in the United States, on Monday, March 11, 1918.

(2) Application blanks and full information concerning these examinations can be procured by addressing "Surgeon-general, U. S. Army, Washington, D. C."

(3) The Dental Corps is a constituent part of the Medical Corps of the army, and consists of officers in the grades of colonels, lieutenant-colonels, majors, captains, and first lieutenants. Appointments therein are made at the rate of 1 for each 1000 of the total strength of the regular army authorized from time to time by law. The law requires that first lieutenants of the Dental Corps shall serve five years in that grade before being promoted, but for the period of the existing

emergency this provision has been suspended by act of Congress, and after one year's service as first lieutenant, a dental surgeon is eligible for promotion to the grade of captain, after which promotions are made in order of seniority as vacancies occur in the higher grades.

(4) No applicant may under the existing law be commissioned in the Dental Corps unless he is between twenty-one and thirty-two years of age, a citizen of the United States, a graduate of a standard dental college, and of good moral character, nor unless he shall pass the usual physical examination required for appointment in the Medical Corps, and a professional examination which shall include tests of skill in practical dentistry and of proficiency in the usual subjects of a standard dental college course. Whether or not the applicant is married has no effect upon his eligibility for the Dental Corps.

(5) Application for appointment must be

made in writing to the Surgeon-general of the Army, upon the prescribed blank form. All the interrogatories on the blank must be fully answered. In compliance with the instructions thereon, the application must be accompanied by testimonials, based upon personal acquaintance, from at least two reputable persons, as to the applicant's citizenship, character, and habits.

The selection of the candidates is made by the Surgeon-general from the applications submitted, and a formal invitation to report for examination to the most convenient examining board in each case will be issued by him.

(6) The examinations are conducted under instructions from the Surgeon-general, and usually last six days. No allowance can be made for the expenses of applicants undergoing examination, whether incurred in travel to and from or during their stay at the place of examination, as public funds are not available for the payment of such expenses.

Each applicant, upon presenting himself to the board, will, prior, to his physical examination, be required to submit his diploma as a graduate of a standard dental college. Should he fail to do so the examination will not proceed.

(7) A first lieutenant receives \$2000 per annum, a captain \$2400 per annum, a major \$3000 per annum. These salaries are increased by 10 per cent. for each period of five years until the maximum of 40 per cent. is reached, excepting that the maximum salary of a major is \$4000 a year, and that of a lieutenant-colonel and colonel is \$375 and \$416.66 per month respectively. In addition to their pay proper, they are furnished with a liberal allowance of quarters according to rank, either in kind, or where no suitable Government building is available, by commutation. Fuel and light therefor are also provided. When traveling on duty an officer receives mileage for the distance traveled. On change of station he is entitled to transportation of professional books and papers, and a reasonable amount of baggage at Government expense. Groceries and other articles for their own use may be purchased from the quartermaster at about wholesale cost prices. Dental surgeons are entitled to medical attendance and hospital treatment without charge other than for subsistence.

(8) Officers of the Dental Corps are entitled to the privilege of retirement after forty years' service, or at any time for disability incurred in the line of duty. On attaining the age of sixty-four, they are placed

on the retired list by operation of law. Retired officers receive three-fourths of the pay of their rank (salary and increase) at the time of retirement.

(9) In order to perfect all necessary arrangements for the examination, applications must be in the possession of the Surgeon-general at least two weeks before the date of examination. Early attention is therefore enjoined upon intending applicants.

FIVE of the candidates who took the examination for commission in the regular dental corps of the army have been reported as qualified. This represents those candidates who could not be appointed because of the age limit if there were any further delay, so they are being commissioned in advance of the others who were examined at the same time, and upon whose qualifications a report will be made later. These officers have been nominated as first lieutenants of the army dental corps, and were confirmed just before the adjournment of the Senate for the holiday recess. Those who are to be commissioned on account of the possibility of age disqualification are Lieuts. John L. Richards, Winfred E. Henshaw, Joseph E. Schaefer, George J. Sibley, and Frank P. K. Barker.

THE legislation of October 6th provides that the dental corps shall be on the same basis as the regular medical corps. Under an opinion rendered by the Judge Advocate-general of the Army, it will be necessary to have examinations for promotion. During the present emergency dental surgeons of the rank of first lieutenant who have served one year in that grade will be examined with a view to advancement to the grade of captain. Promotions to grades senior to that of captain will be made to fill vacancies existing. This means, in the increased corps by virtue of legislation of October 6th, 12 colonels, 20 lieutenant-colonels, and 87 majors. If the present emergency terminates, of course, the first lieutenants of the dental corps will have to serve five years in that grade before promotion. The provision in the law of October 6th for recommissioning of officers of the dental corps provides that they shall be commissioned as first lieutenants, captains, etc., instead of as dental surgeons with the rank of first lieutenant. etc.—*Army and Navy Register*.

ONE of the branches of the army in which there has been a marked increase—something over 1744 per cent.—is that of the dental personnel. When this country entered the war, the army had only 86 dental officers who were members of the dental corps, and of whom 19 were captains and the remainder first lieutenants, and it was necessary to provide an almost entirely new dental personnel to take care of the greatly expanded military establishment. Up to December 15th, 1500 dental officers actually were on duty, of whom 178 belong to the dental corps of the regular army, 227 to the dental corps of the National Guard, and the remainder to the dental reserve corps, this being the number required for an army of 1,500,000 men on the basis of one dental officer to every 1000 men as prescribed for the regular army. Moreover, enough additional dentists have been commissioned in the dental reserve corps, but not placed on active duty, to provide, with those already on duty, a dental personnel for 5,000,000. Owing to enrollment of dentists in sufficient numbers to take care of all anticipated needs, the issue of further commissions was suspended on September 18th, except where men of well-known attainments were required for special duties, and enrollment of the latter class was suspended on December 15th. In carrying on the general dental work of the army, dental surgeons are organized into units, for each of which a dental infirmary is provided. While not permanently assigned to any definite organization, a dental unit ordinarily serves a brigade, with such additional organizations as may be conveniently assigned. Each unit operates under an assistant dental surgeon, selected by the chief dental surgeon of the camp. All dental officers are under the immediate control of the dental surgeon, who in turn is under supervision of the division surgeon. Ordinarily one assistant dental surgeon and ten operating dental surgeons are assigned to each dental unit. The dental division of the office of the Surgeon-general of the Army is in charge of Major William H. G. Logan, medical reserve corps, of Chicago, one of the foremost dental surgeons of the country. He is president of the National Dental Association and chairman of the dental committee of the general medical board of the Council of National Defense. Captains Julien R. Bernheim and John R. Ames, dental corps, are on duty as his assistants.—*Army and Navy Register*.

personnel of the army dental corps will hereafter be 380.

The decision to have first lieutenants serve one year before they are eligible to promotion will retard some of the advancements from that grade. A number of first lieutenants will become lieutenant-colonels as a result of the increase in the corps authorized by the act of October 6th. The one-year service begins with the date of acceptance of commission.

Arrangements are being made for the examination of officers of the dental corps, with a view to their promotion. The first board will be of special composition and consist of a medical officer and two dental surgeons to convene in Washington for the examination of Captains J. R. Bernheim and John R. Ames, who are on duty in the Surgeon-general's office. Upon the qualification of those officers the examining board will be dissolved and a new board convened, consisting of a medical officer and Captains Bernheim and Ames, the former being a colonel and the latter a lieutenant-colonel as a result of the promotions in the corps. Similar boards will be convened at St. Louis, San Francisco, and San Antonio.—*Army and Navy Register*.

Dental Personnel Promotions.

RECOMMENDATIONS have gone from the Surgeon-general of the Army to the chief of staff in regard to advancement of members of the dental corps of the regular army, in accordance with the act of October 6, 1917. This act provides that the dental corps shall consist of commissioned officers of the same grade and proportionately distributed among such grades as are now or may be hereafter provided by law for the medical corps, who shall have the rank, pay, promotion, and allowances of officers of corresponding grades in the medical corps, including right to retirement as in the case of other officers. The act provides also that there shall be one dental officer for every thousand of the total strength of the regular army authorized from time to time by law. Prior to this act, dental officers above the rank of captain were not authorized. In accordance with the recommendations of the Surgeon-general, of the 178 members of the dental corps, 12 will be promoted by seniority to colonel, 20 to lieutenant-colonel, and 87 to major, leaving the remainder in the grade of first lieutenant for the time being. These advancements will take up at least to the grade of major all that were members of the dental corps at commencement of the war, and some that have entered since that time. The

THE authorized strength of the regular army now being 380,000, the commissioned

Surgeon-general's office also is making arrangements to recommend a corresponding reorganization in the dental reserve corps, and to give increased rank to selected officers whose attainments and records warrant recognition.—*Army and Navy Register*.

Dental Corps Promotions.

ORDERS are being prepared directing the convening of boards for examination of members of the regular dental corps due for promotion in accordance with the act of October 6, 1917, which gives that corps the same grades as the medical corps, with distribution in the grades in the same promotion as in the medical corps. This gives the dental corps 12 colonels, 20 lieutenant-colonels, and 87 majors. It will result in the advancement to colonel of captains down to and including Julien R. Bernheim, to lieutenant-colonel of captains, and first lieutenants down to and including First Lieut. Charles deW. Deyton, and to major of the remaining first lieutenants who had at least a year's service on October 6th. Under the requirement of a year's service before a dental officer shall be eligible to advancement, some 54 first lieutenants, down to and including Howard I. Benedict, will become majors, leaving 26 vacancies to the grade to be filled, as officers complete a year's service from time to time. Thereafter, in the same manner, the grade of captain will be filled.—*Army and Navy Register*.

John Nelson White, Green, Ky.
Homer Lash Sams, 1st lieut., D. R. C.; Presidio of San Francisco, Cal.
George Magner Krough, 1st lieut., D. C. of N. G., Camp Cody, Deming, N. Mex.
Wayne W. Woolley, 1st lieut., D. R. C., Camp Cody, Deming, N. Mex.
Edward Wallace Barr, 1st lieut., D. R. C., 6th F. A., 1st Div., A. E. F.

Leslie Albert Gould, 1st lieut., D. R. C., Camp Upton, N. Y.
Harold Avery Curtis, Waverly, N. Y.

The Navy Dental Corps.

APPOINTMENTS have been made to the navy dental corps during the past few weeks, but no more applications will be received by the Surgeon-general of the Navy for some time, since the corps is now in possession of a considerable number of dental surgeons who will be on the inactive list subject to call for service when needed.—*Army and Navy Register*.

New Army Dental Surgeons.

THE following-named applicants for appointment in the Dental Corps of the Army, having passed the required examination, their commissions as first lieutenants in that corps in the following order are recommended.

John Godfrey Urban, 1st lieut., D. R. C.; Schofield Barracks, H. T., Hawaiian Islands.
Carl Stevenson Emmert, 1004 Hume Mansur, Indianapolis, Ind.
William Henry Siefert, 1st lieut., D. R. C.; Fort Omaha, Neb.
Samuel J. Lewis, Kalamazoo, Mich.
James Henry O'Reilly, 1st lieut., D. R. C.; Fort Sam Houston, Texas.
Frederick Werner Miller, Kansas City, Mo.
James Alfred Curtis, Jr., Atlanta, Ga.
James Jay Weeks, 1st lieut., D. R. C.; Camp Cody, Deming New Mexico.

Dental Surgeons Society of Camp Dodge.

AT a meeting of the dental surgeons located at Camp Dodge, Iowa, on November 12, 1917, the following officers were elected: Capt. Frank P. Stone, D.C., honorary president; Lieut. Donald B. Cornell, D.R.C., president; Lieut. Thomas L. Rice, D.R.C., vice-president; Lieut. Stanton L. Sherman, D.R.C., secretary; Lieut. Gerrit H. Hoppers, D.R.C., treasurer.

Renewal of Dental Prostheses.

FOR FRENCH SOLDIERS.

M. JUSTIN GODART, French under-secretary of state for the military medical department, has issued an order by which all aids to mastication (plates, bridges, etc.), furnished to soldiers of all classes to relieve them of digestive disturbances, or which they will use during their enlistment in the army or auxiliary service, will be so furnished only during the period of enlistment; but soldiers who have sustained injuries of the jaws or teeth while in service shall be considered as *mutiles de guerre* (war-mutilated), and will have the right to renew their prosthesis during their lifetime.—*Journ. Amer. Med. Association*.

Assignments.

Army Dental Corps.

Week ending December 22d.

1st Lieut. Walter D. Vail to St. Louis School of Plastic and Oral Surgery, Washington University, for instruction and return to station.

Week ending December 29th.

1st Lieut. Charles L. Andrews from duty at Camp Funston to Austin, Tex., School of Military Aeronautics, for duty.

Week ending January 12th.

John L. Richards, of Minnesota, and 1st Lieuts. Winfred E. Henshaw, Joseph E. Schaefer, George J. Sibley, and Frank P. K. Barker, to dental reserve corps.

Army Dental Reserve Corps.

Week ending December 22d.

1st Lieut. Daniel S. Lockwood to Camp Meade, Md., for duty.

1st Lieut. William H. Delbridge, Jr., to Deming, N. M., Camp Cody, for duty.

1st Lieut. Harold J. McGinn to Garden City, N. Y., concentration camp and supply depot for duty.

1st Lieut. William M. Kester to Wrightstown, N. J., Camp Dix, for duty.

The following to St. Louis, School of Plastic and Oral Surgery, Washington University, for instruction: 1st Lieuts. Ernest E. Buell, Clarence S. DeLong, Edward F. Lefttite, Edward B. Lodge, Walter Sorenson, Pearly M. Fugler, John A. Robinson, and Charles F. Pickering.

Week ending January 12th.

1st Lieut. Harold S. Embree to Camp Cody, N. M., 34th division, for duty.

Stenographers and Typists Wanted—Men and Women.

THE United States Government is in urgent need of thousands of typewriter operators and stenographers and typists. All who pass examinations for the departments and offices at Washington, D. C., are assured of certification for appointment. It is the manifest duty of citizens with this special knowledge to use it at this time where it will be of most value to the Government. Women especially are urged to undertake this office work. Those who have not the required training are encouraged to undergo instruction at once.

Examinations for the Departmental Service, for both men and women, are held every Tuesday in 450 of the principal cities of the United States, and applications may be filed

with the Commission at Washington, D. C., at any time.

The entrance salary ranges from \$1000 to \$1200 a year. Advancement of capable employees to higher salaries is reasonably rapid.

Applicants must have reached their eighteenth birthday on the date of the examination.

For full information in regard to the scope and character of the examination and for application blanks address the U. S. Civil Service Commission, Washington, D. C.; or the Secretary of the U. S. Civil Service Board of Examiners at Boston, Mass.; New York, N. Y.; Philadelphia, Pa.; Atlanta, Ga.; Cincinnati, Ohio.; Chicago, Ill.; St. Paul, Minn.; St. Louis, Mo.; New Orleans, La.; Seattle, Wash.; San Francisco, Cal.; Honolulu, Hawaii; or San Juan, Porto Rico.

JOHN A. McILHENNY,

President U. S. Civil Service Commission,
WASHINGTON, D. C.

To Every American Dentist.

By J. W. BEACH, *Chairman*, Buffalo, N. Y.

President Wilson has asked that every resource for winning the war be utilized to the very limit. The dental profession forms one of the greatest resources for making our army efficient. You are an integral part of this great source of help to your country. Will you meet this responsibility as an American citizen should? Of course you will.

HOW CAN IT BEST BE DONE?

By joining the Preparedness League of American Dentists *now*, and assisting in its great work. Ten thousand new members are needed right away. If you are already a member, we ask you to get five more just as soon as possible. The mouths of the men in our new national army must be made healthy and dentally fit before they go to cantonments, and we must help to the limit of our ability.

The Preparedness League of American Dentists is a recognized agency for carrying on this work under the direction of the Surgeon-general's office of the War department, the National Dental Association, and the Com-

mittee on Dentistry, Subcommittee of the Council of National Defense.

There are forty-five thousand dentists in the United States. Six thousand belong to the League, and have done the major part of the following work: July 16 to November 3, 1917: Fillings 60,946; extractions 35,909; cleanings 2,233; crowns 133; bridges 184; plates 165; unclassified operations 6,891—total 111,061. Thousands of operations not listed were performed prior to and since these dates.

If every one of the 45,000 had done his part, what a splendid showing we could have made! It is not too late to become a part of this great work for increasing the fighting power of our army. We know you are with us.

Don't let the Germans show all the efficiency! Let's show what we can do!

We've got to work together to win this war. Do your part by joining the League *today*, and we will give you real, properly directed work to do.

For membership send one dollar (\$1.00), payable but once, to the Preparedness League of American Dentists, 131 Allen st., Buffalo, N. Y. (Kindly inclose business card to avoid mistakes in name and address.)

SOCIETY NOTES AND ANNOUNCEMENTS

NOTICES should reach the Office of the DENTAL COSMOS not later than the 11th or 12th of the month preceding that of publication.

Psi Omega Fraternity.

ANNUAL BANQUET.

THE twenty-sixth annual banquet of the Psi Omega Fraternity will be held at the Hotel Astor, Broadway and Forty-fourth st., New York, N. Y., Saturday, February 16, 1918, at 7.30 P.M.

All members of Psi Omega are cordially invited to attend.

JOHN L. PETERS, *Treasurer*,
133 West 72d st., N. Y. City.

Marquette Dental Alumni Association.

THE Marquette University Dental Alumni Association will hold the annual clinic in the auditorium, Milwaukee, Wis., February 13, 14, and 15, 1918. A fine program is being arranged.

V. A. SMITH, *Sec'y*,
Milwaukee, Wis.

Vermont State Dental Society.

THE forty-second annual meeting of the Vermont State Dental Society will be held at the New Sherwood Hotel, Burlington, Vt., on March 20, 21, and 22, 1918.

PHILIP E. MELLEN, *Sec'y*,
Middlebury, Vt.

Virginia State Dental Association.

THE Virginia State Dental Association will meet in Roanoke, Va., April 25, 26, and 27, 1918.

F. R. TALLEY, *Corr. Sec'y*,
Petersburg, Va.

University of Iowa, College of Dentistry.

THE dedication of the new dental building of the College of Dentistry, State University of Iowa, will be held February 22d; the Alumni and College of Dentistry Clinic, February 23, 1918, in Iowa City, Iowa.

R. R. DEKRUIF, *Sec'y*,
Des Moines, Ia.

Minnesota State Dental Association.

THE thirty-fifth annual convention of the Minnesota State Dental Association will be held February 7, 8, and 9, 1918, at the University of Minnesota, Minneapolis, Minn.

All members of the National Dental Association are invited. For information, write

MAX E. ERNST, *Sec'y*,
1125 Lowry Bldg., St. Paul, Minn.

Connecticut State Dental Association.

THE fifty-fourth annual meeting of the Connecticut State Dental Association will be held at the Hotel Taft, New Haven, Conn., April 18, 19, and 20, 1918.

GEO. S. B. LEONARD, *Sec'y*.

Texas State Dental Society.

THE thirty-eighth annual convention of the Texas State Dental Society will be held at San Antonio, Texas, the famous City of the Alamo, April 10, 11, and 12, 1918. Members of other state societies are cordially invited to attend.

J. G. FIFE, *Sec'y*,
736 Wilson Bldg., Dallas, Texas.

Pennsylvania State Dental Society.

THE golden anniversary meeting of the Pennsylvania State Dental Society will be held in Wilkes-Barre, April 23, 24, 25, and 26, 1918. Excellent talent has been secured for the occasion and the program extended to a four days' session. To judge by preliminary reports of committees, this event promises to be the greatest meeting in the history of this organization. All ethical practitioners are cordially invited to attend.

J. F. BIDDLE, *Sec'y*.
517 Arch st., Pittsburgh, Pa.

North Carolina Dental Society.

THE North Carolina Dental Society will meet on June 19 to 21, 1918. Headquarters, Oceanic Hotel, Wilmington, N. C.

W. T. MARTIN, *Sec'y*.

Kentucky State Dental Association.

THE next annual meeting of the Kentucky State Dental Association will be held at Lexington, Ky., June 13, 14, and 15, 1918. An "amalgam program" of special interest.

Address all correspondence to

W. M. RANDALL, *Sec'y*,
1035 Second st., Louisville, Ky.

Kansas State Dental Association.

THE annual meeting of the Kansas State Dental Association will be at Topeka, Kans., on April 15, 16, and 17, 1918.

C. K. WEAVER, *Sec'y*.
Clay Center, Kans.

Odontological Society of Western Pennsylvania.

THE thirty-seventh annual meeting of the Odontological Society of Western Pennsylvania will be held in the Hotel Chatlam, Penn. ave. and Fourth st., Pittsburgh, Pa., Tuesday and Wednesday, April 9 and 10, 1918.

The Program Committee promises one of the best dental meetings ever held. Men of note will read papers of interest to the twentieth-century dentist.

The clinics will be given by the study clubs of Western Pennsylvania, and will be of interest to one and all.

Exhibitors will be amply accommodated with space by addressing Dr. Leslie Waddill, Jenkins Arcade Bldg., Pittsburgh, Pa.

KING S. PERRY, *Sec'y*,
719 Jenkins Bldg., Pittsburgh, Pa.

Illinois State Dental Society.

THE fifty-fourth annual meeting of the Illinois State Dental Society will be held at Bloomington, Ill., May 14, 15, 16, and 17, 1918.

J. E. HINKINS, *President*,
Chicago, Ill.

J. P. LUTHRINGER, *Sec'y*,
Peoria, Ill.

Maine Board of Examiners.

THE Maine Board of Dental Examiners will hold a special examination, beginning February 19, 1918, at 8.30 A.M., at the State-house.

All applications and fee of \$20 must be in the hands of the secretary by February 9, 1918.

WILL S. PAYSON, *Sec'y*,
C'astine, Me.

Massachusetts Board of Examiners.

A MEETING of the Massachusetts Board of Dental Examiners will be held in Boston, Mass., February 11 to 15, inclusive, 1918, for the examination of candidates for registration. All applications must be in the hands of the secretary on or before February 2d. For further information address

GEORGE H. PAYNE, *Sec'y*,
29 Commonwealth ave., Boston, Mass.

Mississippi Board of Examiners.

THE Mississippi Board of Dental Examiners will hold its next annual meeting at the State Capitol building in Jackson, on the third Tuesday in June 1918, at 8 A.M. Fee for examination \$10. Practical and written examinations. Diploma from recognized school and certificate of moral character required. No reciprocity or interchange. For further information, address

B. J. MARSHALL, *Sec'y*,
Marks, Miss.

Forsyth Dental Infirmary for Children.

NEW DEPARTMENT—LIBRARY AND MUSEUM.

THE trustees and director of the Forsyth Dental Infirmary for Children have authorized the creation of a new department, to be known as the "Library and Museum." They solicit from the dental profession contributions of books and dental periodicals, particularly those out of print and not readily obtainable by purchase; also specimens of dental abnormalities, casts, or specimens of unusual structures of dental interest, for all of which permanent acknowledgment will be given.

FREDERICK A. KEYES, D.M.D.,
Librarian and Curator of Museum.

National Mouth Hygiene Association.

DEPARTMENT OF EXTENSION LECTURES.

A COMPLETE lecture set, consisting of full manuscript and thirty-six specially selected and prepared lantern slides covering the subject of Mouth Hygiene, is furnished by this association to members of state dental societies and others who may be considered as qualified to present the subject on the lecture platform.

For rental and sale terms and other particulars address the undersigned.

EDWIN N. KENT,
Director of Extension Lectures,
330 Dartmouth st., Boston, Mass.

ORIGINAL COMMUNICATIONS

The Relationship of Oral Secretions to Dental Caries.

II. Conditions Influencing the Quantity and Action of the Amylase Content of Human Saliva.

By HERMANN PRINZ, D.D.S., M.D., Philadelphia, Pa.

From the Laboratory of Pharmacology, Evans Institute, Univ. Pennsylvania.

(Continued from page 147.)

NUMEROUS attempts have been made in the past to discover some tangible method for the purpose of determining the influence of extraneous causes, such as psychic influences, nervous irritants, and especially food-stuffs, on the amylase content of saliva. Without entering into a detailed discussion of the literature on the subject, let it suffice to say that the more recent investigators (and their many co-workers) may be enumerated as follows: A. L. Chittenden, J. P. Pawlow, J. N. Langley, C. L. Evans, L. Michaelis, J. Wohlgemuth, H. P. Pickerill, and others too numerous to mention. By a careful perusal of the enormous mass of literature of the last fifty years, one is primarily impressed with one singular fact,

i.e. that a number of investigators have approached the subject from a teleologic point of view, and hence have failed to solve the problem. For instance, if we merely feed an experimental subject (and parenthetically it should be emphasized that the subject for the purpose under consideration must be a human being and not an animal, since results drawn from such comparative experiments for numerous reasons are frequently misleading) and examine the amylase content of the saliva during and for some time after the various test meals, only comparative results are obtained which do not portray the actual working conditions of this amylase content.

The fundamental question which *a pri-*

ori confronts the investigator may be formulated as follows: What working conditions influence the quantity and the action of the amylase content of human saliva? Within limitations, the amylolytic index of human saliva is constantly changing during the various periods of the day. The flow of saliva is solely dependent upon nervous impulses. These impulses are primarily of a mechanical or chemical nature, although psychic impulses, *i.e.* fear or the sight of tempting food, have also to be reckoned with; and again, the action of specific drugs, *e.g.* atropin, pilocarpin, nicotin, markedly affect the salivary secretion. These latter conditions, however, do not play any part in our present consideration. The quantity and to a large extent the quality of secreted saliva are, within certain limits, directly proportional to the intensity of the irritant, primarily foodstuffs, and the mechanism of the masticatory process. Regarding the nervous impulses which control the flow of saliva (or any other glandular secretion) physiologists as yet have not definitely settled which of the two leading theories, that of Heidenhain or that of Langley and Carlson, is the correct one. Heidenhain maintains that with the increase of the ratio of flow the content of salts in the saliva is also increased, the greater the quantity of the secretion the higher being the amount of inorganic constituents. Langley and Carlson, on the other hand, claim that the secretory function of the gland is dependent upon the specific nature of the blood pressure. Accepting the correctness of these two theories for the present, we may assume that any substance entering the oral cavity irritates the endings of centripetal nerves which control the secretion of saliva. Depending upon the quality of the irritant the resultant impulse is conducted to the various parts of the glandular tissue, and thereby causes a flow of saliva of a specific composition. However, it has been demonstrated by Pawlow that if a dog with a gastric fistula is fed a carbohydrate "sham meal," in which food is chewed but not swallowed, no change in the amylase content of the saliva is ob-

served while, on the other hand, if the same meal be swallowed, the amylase content proportionally increases. These experiments have been verified by C. L. Evans and in our laboratory. Bayliss and Sterling have furnished a plausible explanation of this most interesting phenomenon. According to these observers, the absorbed foodstuffs act as chemical activators of certain bodies known as hormones, which in turn call forth the secretion of a saliva especially adapted for the respective foodstuffs.

According to carefully conducted experiments by Pawlow and his pupils, the working conditions which govern the flow of saliva may be summarized as follows: The functions of the salivary glands are judiciously adapted to the respective needs, a condition which may be termed "purposiveness." The secretion of saliva occurs only when actually required; it may be caused by the irritation of substances having entered the oral cavity, and to a less extent by the sight of these substances or by psychic impressions. If foodstuffs intended to be swallowed have entered the mouth, a thick, viscid saliva, rich in mucin, is secreted, which lubricates the food bolus and facilitates its ready passage into the stomach. If, on the other hand, substances are brought into the oral cavity which are not intended as foodstuffs but are harmful, a thin, watery secretion is produced which is calculated to dilute such substances and to aid in expelling them from the mouth. The parotid glands do not secrete saliva rich in mucin, but their product is rich in its content of amylase and other ferments. If acids are brought into the oral cavity the parotid glands quickly pour out a large quantity of saliva rich in alkaline bases and albumin which is designed to dilute the acids. (See Table 2.)

It has also been established that the quantity and the quality of the secretion of all the salivary glands are most markedly influenced by the degree of dryness of the foodstuffs: the dryer the foodstuffs the more rapid the secretion of saliva. The influence of the degree of dryness of the foodstuffs is especially

noticeable in its relation to an increased activity of the parotid glands. There seems to exist a direct interdependence between the rapidity of the flow and the

While the above-noted deductions of Pawlow have been observed in animals with artificially established salivary fistulas, Mitscherlich in 1832, and Za-

quantity of the chewed foodstuffs within a given period of time, *i.e.* the quantity of the irritant. (See Table 3.) A similar interrelationship is also to be observed in regard to the flow of the gastric and pancreatic juices.

browski in 1905, have verified these findings in human beings having pathologic salivary fistulas of the parotid glands. The chewing of hard toasted bread, according to these investigators, called forth a quantity of saliva which was twice

as great as that obtained by chewing an equal amount of soft wheat bread within the same period of time. These data virtually conform to the tables of Pick-erill and other observers, and are in accordance with our own observations. Relative to the composition of the secreted saliva, it was observed that, in accordance with the law of Heidenhain already referred to, the quantity of inorganic salts is increased with the rapidity of the flow as a consequence of the increased intensity of the irritant. On the other hand, the quantity of organic constituents is greater in a slow-flowing saliva, on account of the lessened intensity of the irritant. After a prolonged period of fasting, saliva is usually rich in organic substances.

Carbohydrates, as a rule—depending, however, on the physical and chemical structure of their make-up, *i.e.* moisture, compactness, acid or alkaline reaction, etc.—produce a saliva rich in organic substances, principally amylase, while a pure albumin (protein) meal produces a saliva which shows no increase in its amylase content over resting saliva. As an illustration of the ready adaptability of the function of the salivary glands, the following experiment may be cited: A house-dog was fed on a pure meat diet for a month. Upon examination it was found that his saliva was practically free from amylase. This fact is merely in conformity with the absence of amylase in the saliva of purely carnivorous animals. The same dog was next fed on a mixed diet of table scraps containing potatoes, bread, bones, and meat, and the presence of amylase was shown within a week after the dietary change. Indifferent liquids, as water, milk, tea, physiologic salt solution, etc., practically do not induce a flow of saliva; this is equally true in regard to indifferent substances taken into the mouth, as pebbles, sand, glass beads, etc. Acids, on the other hand, always call forth a most rapid flow of saliva rich in organic substances as well as in inorganic salts. Weak alkalis, diluted alcohol, and bitter substances do not materially increase its flow.

A most pronounced indirect stimulation of salivary secretion is produced by the act of mastication. Chewing as such, *i.e.* masticatory movements without the presence of food in the mouth, does not materially alter the flow of saliva. On the other hand, the chewing of food markedly augments the flow of saliva, by the action of the stimulating properties of the chemical and physical characters of the food bolus, by an increase of the aggregate activity of the stimuli in the bringing of the food particles over and over again into contact with the various regions of the oral cavity, and by insuring close contact of these same food particles with the taste-buds situated in the deep fissures of the circumvallate papillæ. The process of mastication is not merely dependent upon the crushing stress of the teeth, but equally so upon the simultaneously exercised muscular movements of the tongue and the cheeks. In this connection it is of interest to note that in a case reported by Jurasz, of idiopathic xerostomia (dry mouth), a rare disease affecting the functions of the salivary glands, a free flow of saliva was re-established after the insertion of a full set of artificial teeth. Apparently the trouble was started by the inability to masticate through the complete absence of the teeth.

The enzyme action of salivary amylase depends, aside from moisture and a specific temperature, primarily upon the presence of certain ions; salivary amylase is absolutely inactive in a medium deprived of its salts. This is equally true of the action of the salivary ferments of less importance, *i.e.* maltase, catalase, and oxydase. The following experiment will amply verify this statement: First, the amylolytic index of a sample of freshly secreted saliva is determined. Five cc. of the same saliva is placed in a tested Abderhalden diffusion shell, covered with a few drops of toluol to prevent decomposition, and dialyzed against distilled water. The water is changed twice a day for about a week. About 50 cc. of a 1 per cent. soluble starch solution is dialyzed against distilled water for three or four days. (See diagram.) The amylolytic in-

dex of the dialyzed saliva and starch is now ascertained, and it will be found to be practically *nil*. Absolute inactivity of amylase is rarely obtained by this process, as the last traces of sodium chlorid, its principal activator, are removed only with the greatest difficulty. If a 1 cc. sample of this same dialyzed saliva is geometrically diluted with physiologic salt solution (0.85 NaCl), according to the method described in the previous paper,* and tested with a starch solution, it will be observed that the saliva has regained its normal activity. Its amylolytic index will be practically the same,

or even higher than that of the undialyzed sample. If the dialyzed saliva is tested in the presence of sodium nitrate solution, it will be noticed that this latter substance also powerfully activates the amylase, while sodium sulfate, sodium phosphate, and sodium acetate possess very little activating influence.

Roger has stated that phosphates are absolutely necessary for the action of amylase: the writer cannot verify this statement. Roger further states that human saliva is not activated by heating for ten to fifteen minutes at 90° to 100° C., but that if a small quantity of fresh saliva be subsequently added the mixture has a much greater saccharifying action than the added saliva alone. In the writer's opinion this increased activity of the added saliva is due to the NaCl content of the boiled specimen, as

described farther on. Incidentally, as Michaelis has pointed out, if a mixture of sodium chlorid and sodium nitrate be employed as a diluent of the dialyzed saliva, each substance being a strong activator, they behave in their combined action as paralyzers. It is to be observed that only the anion of the various salts is concerned as the activating factor; the cation, in all probability, plays no part in the process. Apparently there exists a certain affinity between the anion of the respective salt and the amylase, forming a more or less labile complex compound which as such acts upon the starch molecule. The activity of the newly formed salt-amylase compound is primarily dependent upon the concentration of the anions of the surrounding medium, *i.e.* the dissociation constant of the acid anions, which in turn determines the reaction of the solution. In other words, the hydrogen ion concentration $[H^+]$ of the medium determines the activity of the salivary amylase.

Salivary amylase, being an organic compound, is completely destroyed by heat; severe cold does not harm it to any appreciable extent. Amylase is extremely sensitive to the presence of acids and alkalis, even in mild dilutions. However, very dilute acids, and to a less extent alkalis, act as activators. In round figures it may be stated that an equivalent of 0.015 per cent. HCl on the acidity range and N/1500 NaOH on the alkalinity range will kill amylase. Carbon dioxid (CO_2) in a neutral solution acts as a paralyzer; in the presence of alkalis, as in freshly secreted saliva, it partially neutralizes these alkalis and acts indirectly as an activator. Human saliva may be defined as being a weak solution of alkalis, as present in the body juices, these being more or less saturated with carbon dioxid. When saliva is exposed to the atmosphere, most of the carbon dioxid is given off, hence the difference between the amylolytic index of a fresh specimen and that of the same specimen after a few hours of exposure. As we have stated above, the presence of certain neutral salts alters the activity of the salivary ferments most markedly.

* See DENTAL COSMOS, February issue, page 140.

Of primary interest in this connection is to be noted the most remarkable influence which sodium chlorid plays as an activator. The same action is shared by many other soluble chlorid salts, *i.e.* potassium, ammonium, barium, calcium, magnesium, etc. The increase of the activity of the amylase by the addition of reasonable quantities of sodium chlorid corresponds to about five to six times its normal action; occasionally, however, we have observed an increase of about twenty times the normal. The lowest dilution of sodium chlorid which exercises any perceptible influence corresponds to a concentration of about 0.001 per cent., while its optimum may be placed at about 0.5 per cent. In eating salt-free breadstuffs, unconsciously we reach for the salt-cellar to facilitate the ready munching of the sticky food bolus by rendering it more "palatable." In reality, we activate the salivary amylase to its optimal point, and thereby quickly change the tasteless, pasty mass into a sweet-tasting semi-liquid mixture.

To readily comprehend the rôle which the hydrogen ion concentration plays in regard to the activities of salivary ferments, it is essential to possess at least a passing acquaintance with the laws governing this interesting phase of physical chemistry. "Water is an electrolyte, and dissociates into H^+ and OH^- ions, which are therefore equal in number. At 22° or 23° C. $H^+ = OH^- = 10^{-7}$, or $H^+ \times OH^- = 10^{-14}$. If we increase H^+ by adding acid, OH^- decreases, because $H^+ \times OH^-$ remains equal to 10^{-14} . Conversely, if we add alkali, H^+ decreases, and hence we may estimate the acidity or alkalinity of a solution by determining the H^+ concentration. The product of the H^+ and OH^- ion concentrations is 10^{-14} , and the —logarithm is 14 (and is designated —log K_w). In order to save space it is better to express H^+ concentration as the minus logarithm (PH). Thus, according to Sørensen, if H^+ con-

centration = 10^{-7} , $PH = 7$ " (J. F. McClendon.) In other words, the absolute neutral point of the purest type of distilled water at about 22° C. corresponds to $PH\ 7$.

While in a future article we intend to discuss the reaction of saliva somewhat in detail, it is essential for the ready comprehension of the conditions which govern the action of its enzyme contents to state at this point that freshly secreted human saliva may be looked upon practically as a neutral liquid having usually a very faint inclination to the acid range. Its slight variations either on the acid or alkaline side of the neutral point are so minute that they do not interfere to any appreciable degree with the action of its contained ferments.

A given ferment usually reaches its maximum activity at a specific constant of H^+ ; this point is known as the isoelectric constant, and is expressed as the optimum PH of the ferment. The optimal hydrogen ion concentrations at which the so-far isolated salivary ferments develop their maximum activities as measured by the gas chain method are as follows:

| Ferments. | Optimal PH. |
|----------------|-------------|
| Amylase | 6.7 to 6.9 |
| Maltase | 6.1 to 6.8 |
| Catalase | 7 |
| Oxydase | 7 |

As the H^+ ion concentration of a given medium also indicates its reaction, *i.e.* whether the medium reacts acid or alkaline, it is to be concluded from the above table that the optimum activities of the salivary ferments hover very close about the neutral point, with a faint inclination toward the acid range. This specific reaction, in turn, corresponds to the average reaction of freshly secreted human saliva.

40TH AND SPRUCE STS.

(To be continued.)

A Simple Form of Removable Bridge Work with Cast Clasps.

By NORMAN B. NESBETT, D.M.D., Boston, Mass.,

INSTRUCTOR IN INLAY WORK, HARVARD UNIVERSITY DENTAL SCHOOL, SPECIAL LECTURER
COLUMBIA POSTGRADUATE SCHOOL OF DENTISTRY.

(Read before the annual meeting of the Northeastern Dental Association, Worcester, Mass.,
September 26 to 28, 1917.)

THREE years ago, on February 10, 1914, I began experiments which led to the perfected technique I am now bringing before this meeting. It seemed reasonable that some simple and effective form of removable bridge could be devised to fill in the middle ground between the complicated and successful but necessarily very expensive types of removable bridges, of which the Peeso is the best example, and the frequently inefficient, cheaply made vulcanite appliances with spring clasps of wire or clasp metal.

That the dental profession was in great need of such an appliance has been best evinced by the interest shown since I began my experiments and first exhibited some completed bridges. The appliance has replaced in many cases pieces of fixed bridge work and bent-clasp appliances, and in every instance of this kind the patient has reported more comfort and efficiency in chewing food. And, after all, gentlemen, you must realize that the patient has the final word on this subject.

At different times during my seventeen years of dental practice attempts had been made to furnish a substitute for one lower left first molar which I was unfortunate enough to lose in my youth. The only stipulation I made, as the abutment teeth were comparatively sound, was that they should not be cut into or ground, except a very little on the occlusal surfaces to allow for lugs. This of course barred all inlay, pin and plate and other attachments of like na-

ture. Most of the appliances made for my case seemed to fit very nicely until I began to chew on them, and then they behaved in anything but a pleasant manner. Some would not stay in place; some, under any ordinary pressure, would be forced down and cause much discomfort; some broke after several weeks' use—and all were so generally unsatisfactory that I preferred to

FIG. 1.

be without them. Nearly all the operators who tried to solve the problem said that I expected too much of any removable appliance made with clasps. I, however, did not think so, and concluded that I would make a few experiments with cast clasps, and the appliance which I have been wearing with comfort and efficiency for three years is the result of those experiments. (See Fig. 1.) Again, as I said before, the patient has the final say as to whether or not an appliance for *chewing* is efficient. I was the patient, so I *know*!

It has been my privilege, during the

three years I have been working out the technique of this bridge, to make them for several dentists to use in their own mouths, and for the patients of about twenty different dentists. I consider the report of some eighty-odd cases taken this way to be of more value than if they were all from one dentist's practice. It has also proved conclusively that the indirect method employed in making the bridge was successful, provided the steps were carried through correctly. I know this has been questioned quite a little since my first paper on this subject appeared. But in every instance

lugs at this time, if it does not exist. Next, an accurate plaster impression is taken, and this is the keystone of the whole process, for these cast clasps have practically an inlay fit, and under no circumstances should attempts at bending be made to correct any error in fit.

A small swivel crown and bridge tray is oiled. The impression plaster used must be mixed much thinner than for other impression work, as we wish to obtain sharpness and definition in all our tooth lines, and the stiffer mix of plaster will not flow into undercuts caused by tipped or leaning teeth. When

FIG. 2.

where the practitioner has taken a *correct* plaster impression and obtained a *correct* bite, the bridge has gone to place with little or no adjusting, and has been useful from the first hour.

TECHNIQUE OF MAKING THE CLASP BRIDGE.

The following is the technique I have worked out, which can be used by any man with a correct knowledge of gold casting, who knows how to handle plaster and is familiar with the use of correct soldering investment and blowpipe. I must say right here, however, that the construction is *not* easy, and requires the utmost attention to detail and care in every step of the process.

The patient's teeth to be clasped are cleaned and polished, and the occlusion noted, as space must be provided for the

the plaster has *started* to set, the tray is removed, and the plaster scored at suitable points so that it can be removed in sections. The plaster is allowed to complete its setting to the point where it will break with a clean, sharp fracture. The resulting sections are then removed. Several impressions must be taken in some cases having long tipping teeth before one accurate enough to be used can be obtained. Under no circumstances should an attempt be made to use a carved or otherwise "faked" model, as failure or only partial success will surely result. Next, a modeling compound impression of the opposing teeth and a small guide bite in wax are taken (Fig. 2), and the shade of teeth noted. If this data is accurately obtained the patient need not be seen again until the bridge is completed.

The plaster impression should be put together as soon as it is fairly dry, using the tray for a matrix or guide, for the proper position of the pieces. Personally, I find it almost impossible to get the pieces in their proper places without some slight distortion, unless I replace them in the tray and wax them to place with sticky-wax. The impression is coated lightly with shellac, then with sandarac varnish, and is set aside to harden. The teeth to be clasped are made removable, and are packed with amalgam, sinking small dowels in the amalgam before it begins to set. Care

FIG. 3.

should be taken to shape and smooth these dowels so that they will draw easily, and to set them as nearly parallel as possible, so that both teeth, no matter how badly tipped, can be removed in the same plane. After the amalgam has set, the dowels are oiled and the balance of the impression packed with Weinstein's artificial stone. Plaster can be used for this purpose, but the artificial stone gives a more satisfactory working surface. The compound impression is also poured, and the two resulting models are mounted on an anatomical crown and bridge articulator, using the wax guide bite to establish occlusal relations. (See Fig. 3.)

We now have a correctly articulated model with two removable amalgam teeth, having their dowel pins in the

same plane so that both teeth can be removed freely. The clasps are then outlined on the amalgam teeth, waxed up and cast. The casting is done in a cold mold, with a Taggart oxyhydrogen machine, the Taggart technique being followed throughout. After freeing the clasps from all adhering investment they are boiled in an acid bath, and smoothed and fitted to the teeth, which, being removable, make this part easier. An Ash tube tooth of proper shade is ground so as to leave sufficient thickness for a saddle. I prefer the Ash tube teeth for this type of work, because they enable me to use a maximum amount of porcelain with a minimum weight

FIG. 4.

of gold framework, and because, when ground for correct shape and occlusion, they can be beautifully polished. The type of bicuspid and molar known as the Davis crown for metal work can also be used to good advantage.

The middle section, comprising the saddle, cup for porcelain, and post, is then cast. Usually, I prefer for a post a high-fusing clasp-metal wire, No. 15 gage B. & S., picked up in the casting and afterward made doubly secure with a bit of solder. After cleaning and pickling, this middle section is placed in proper relation to the clasps on the model, plaster relations of the parts are taken, and the three parts assembled with one soldering. (See Fig. 4.) The framework is then tried on the model (the removable teeth making this easy), and any error in fit resulting from the soldering process corrected, if necessary.

To secure the best results, the joints between the clasps and the middle section

FIG. 5.

should be quite close, so that only a small amount of high-fusing solder will

FIG. 6.

be required to make a very strong union. If the clasps are as accurately fitted as they should be, any very slight change during the soldering will disturb the relations of the three sections so that they cannot be placed in correct position, and

large mass of casting-wax without distorting the clasps. When the framework is found to fit on the model as desired, the porcelain tooth is cemented to place, and all metal work nicely smoothed and polished. (See Figs. 5, 6, and 7.) The appliance is again placed on the model and final adjustments for occlusion are made. This done, the ground surfaces of the porcelain are polished, and the bridge is ready for the patient. As stated before, if proper care and attention have been paid to every step, the bridge should require but little adjusting at the chair.

METALS USED IN MAKING THE CLASP BRIDGE.

Now just a few words as to the proper metals to be used for this bridge. It has been reported, from time to time, by various authors on dental subjects that cast clasps have no resilience, and are very brittle. This, I believe, is because the investigator confined his experiments to attempts at casting the ordinary clasp metals, high in copper content, which *are admittedly very brittle and unreliable* when exposed to the high heat neces-

FIG. 7.

the resulting appliance will not prove satisfactory.

Under no circumstances should the attempt be made to cast the two clasps and middle section in one casting, for while this can easily be done, no *proper clasp fit* can be obtained. The warpage and distortion of such a large irregular casting is *uncontrollable*, to say nothing of the impossibility of removing such a

sary for casting. After quite a bit of experimenting with different formulas of clasp metal, it finally occurred to me to try Ney's elastic gold, and with the valuable assistance of Mr. L. J. Weinstein of New York, we finally evolved a new alloy for casting clasps, now known as Ney Oro casting gold "E." This metal is a combination of two of the new Weinstein formulas, known as Elastic

gold and No. 68 solder. It is nearly platinum-white in color, is unchanged by any oral secretions, making a hard, dense casting free from flaws, with considerable elasticity. It has a melting-point of approximately 1954°F. , about the same as pure gold. The formula is—Gold, 65; silver, 4; copper, 9; platinum, 8.5; palladium, 12.5; zinc, 1. About 75 per cent. of all my cases have clasps made of this metal, and no breakages have been reported to date.

The middle section, carrying the porcelain, is cast with a platinum and palladium gold alloy, known as Ney's casting gold "B." the percentage formula for which is—Gold, 80; silver, 1; copper, 7; platinum, 9.50; palladium, 2.50. Melting-point, 1900°F. I prefer this alloy because it is untarnished by any oral secretions; does not appreciably change form in casting, and because 22-k. or No. 84 solder can be used without fear of melting even thin edges of the casting. The use of these high-heat solders is a distinct advantage, as it enables the operator to obtain a stronger joint, and one that does not oxidize and mar the appearance of the work in a short time. It is a well-known fact that 18-k. solder will oxidize very rapidly in some mouths, and leave a dark, unsightly joint.

ADVANTAGES CLAIMED FOR THIS TYPE OF BRIDGE.

(1) No devitalization of pulps, and usually no necessity of grinding the enamel surfaces of the teeth.

(2) An appliance that can be easily removed and cleaned by the patient. Has no troublesome tubes, slots, or sockets to be kept cleaned out, as in other forms of removable bridges.

(3) Has a maximum of stability and food-grinding surfaces.

(4) Can be constructed with a minimum of nervous strain to the patient and the dentist.

(5) Can be constructed by any operator who can construct a well-made fixed bridge; but cannot be "made to go" if carelessly constructed by the type of

operator who cannot make a good fixed bridge, but who "gets away" with it because it can be jammed on with cement—and cement hides a multitude of sins!

(6) Is almost universal in application where there are two solid teeth that can be utilized, as parallelism of abutments is not necessary.

DISADVANTAGES.

The disadvantages can be summed up under one head, namely, liability of injury to the enamel surfaces under the clasps. We should select our cases for this appliance with great care, and not blind ourselves or our patients to the fact, long ago explained by Dr. Bonwill, that dissolution of the enamel and caries of the dentin under this or *any other type of clasp* will take place unless strict attention to cleanliness is observed. The fact that this type of clasp does not allow room for any appreciable amount of food debris to crowd between it and the enamel of the adjoining tooth should not lure us into a false sense of security when it is used on teeth of soft and chalky structure, or when the toilet of the mouth is neglected. I believe that with proper care and watchfulness on the dentist's and on the patient's part, time will show that no great amount of damage will occur under the clasps. And, granting that it *does* occur, can it not be easily repaired with the many methods that we have at our disposal? Surely such small damage that may come will be of less moment than the serious results that are coming from devitalized teeth, and of the two evils I, for one, am prone to choose the lesser.

In conclusion, I wish to say that this technique will not appeal to the man who wants "hurry-up" results, or who expects that this form of bridge can be constructed for a small fee. A careful tabulation of the working time required in an average case shows one hour of chair time to get data and adjust the bridge, with instructions to patient as to its care, and from six and one-half to eight hours' laboratory time.

It will, however, appeal to any patient

who has lost teeth through failure of fixed bridge work, or who has sat for hours in a dentist's chair having his teeth and roots prepared for other forms of either fixed or removable bridge work. And in this era of strenuous hustle, the

patient's time is a factor that will have to receive some consideration.

[See also *Discussion*, as reported under "Proceedings of Societies," this issue.]

Selection of Anesthesia for Oral Surgical Operations, and the Roentgen Ray as an Aid in Diagnosis.

By KURT H. THOMA, D.M.D., Boston, Mass.,

LECTURER ON ORAL HISTOLOGY AND PATHOLOGY, HARVARD UNIVERSITY DENTAL SCHOOL;
INSTRUCTOR IN DENTAL ANATOMY, HARVARD MEDICAL SCHOOL.

(Read before the Northeastern Dental Association, at its annual meeting, Worcester, Mass., September 26-28, 1917.)

BEFORE undertaking an operation in the mouth it is important to see the patient for the purpose of making an accurate diagnosis and selecting the most suitable form of anesthesia. The two principal types from which to choose are local and general.

It is not my intention to go into details of technique, but rather to confine myself briefly to a discussion of the different points which are helpful in the selection of an anesthetic.

For operations to be performed in the office, where it is difficult to prepare the patient properly, local anesthesia is preferable. It has the advantage of freeing the region of the operation from the presence of the anesthetist and his appliances; also it eliminates the dangers attending general anesthesia, that is, swallowing and inspiration of blood and pus. Then, too, the absence of vomiting after the operation is a point in its favor, as there is no disintegration of the wound by the vomitus. Furthermore, with local anesthesia the co-operation of the patient is possible, and the hemostatic action of the injection makes the field almost bloodless, both of which

factors facilitate the work of the operator.

Notwithstanding these great advantages we must nevertheless select our cases for local anesthesia. Children are usually poor subjects, although very intelligent older children prove to be exceptions in some cases. Among adults we have those who will not consent to anything but a general anesthetic, but for many patients a general anesthetic is contra-indicated. In such cases danger can be avoided by the use of local anesthesia.

The excitable, nervous, timid patient who dreads knowing what is going on and is afraid of the instrumentation can sometimes be taken care of by pre-anesthetic medication, such as bromural, veronal, or morphia, but as a rule does better under a general anesthetic.

The majority of dental and oral surgical operations can be performed with the intra-oral method of local anesthesia, while the extra-oral method is indicated for all extensive cases where a large area is to be anesthetized, and where the use of the intra-oral method would necessitate injection into pathological tissue.

The most commonly used intra-oral methods are the zygomatic, infra-orbital, palatal, and pterygo-mandibular injections. The principal extra-oral injections are the infra-orbital, maxillary, and mandibular.

If general anesthesia is used in oral surgery we have the choice between nitrous oxid and oxygen, ether, and a

receives ether applied with a cone, and when sufficiently relaxed, ether vapors are administered by a pump into the pharynx, either from a tube extending back into the mouth or by the insertion of a naso-pharyngeal tube, which extends into the naso-pharynx.

Another way is the intra-tracheal method, which is very satisfactory, but

FIG. 1.

combination of the two. Nitrous oxid and oxygen has been used so long for short operations that it needs no further recommendation. However, it does not always insure an uninterrupted operation, even if administered by an experienced anesthetist, especially if the operation is of long duration. I therefore prefer ether given by one of the newer methods, as a perfect continuous anesthesia can be obtained with it. After anesthesia is induced by nitrous oxid and oxygen the patient ordinarily

more difficult in its application. The tubes are passed through each nostril into the nose and pharynx and from there into the trachea, the ether being given through a funnel filled with gauze, and connected to the intra-tracheal tubes by a larger piece of rubber tubing. The patient inhales air saturated with ether vapors, and care must be taken that no liquid ether is allowed to enter the lungs.

Large oral surgical operations should only be undertaken in a hospital, and never in an office, as it is not fair to

give a patient general anesthesia without proper preparation and after-care. As many of our operations require special apparatus, it is the general tendency to undertake too much in the office. In order to overcome this I have equipped for my purpose an operating room for oral surgical operations at one of our private hospitals, and find that patients are very appreciative of the care they receive before and after the operation, especially if they come from out of town.

In operations performed under a general anesthetic it is advisable to use an aspirator to take up the saliva and blood, and the conditions can also be improved by employing a combination of local and general anesthesia. This not only does away with the surgical shock, but by decreasing the amount of bleeding clears the field of operation.

Quite as important as selecting the anesthetic is the making of a correct diagnosis. The roentgen ray is the most important means of making an examination, and in a great many cases it gives exact and accurate information. It should not, however, be entirely relied upon, and a study of the history and symptoms of the case should not be overlooked.

For lesions of the jaws and unerupted third molar teeth extra-oral plates are preferable. The small area covered by a film is quite often insufficient and misleading in its information, especially if a tooth is misplaced or if the lesion is extensive. The object to be roentgenographed should not only have its entire outline shown, but an idea should be given of its proximity to adjacent structures, and enough of the surrounding normal tissue should appear in the plate to make possible a contrast between it and the parts affected by disease.

DIFFICULT EXTRACTIONS, IMPACTIONS, AND EXOSTOSES.

The extraction of impacted teeth is one of the most common oral surgical operations, and a good roentgen picture is absolutely necessary to plan the procedure by which it can be removed with

the least injury to the remaining tissue. I prefer extra-oral plates for impacted third molars, but occasionally a film will

FIG. 2.

suffice. However, a negative finding on the film should always be verified by a plate, unless there is a history that the tooth has been removed. Quite fre-

FIG. 3.

quently third molars are situated so far away from their normal positions that they would not come into the intra-oral picture, and this might lead to the

FIG. 4.

conclusion that the tooth was congenitally absent. Such a case is shown in Fig. 1. Here the film showed no third molar whatever, while on the plate it is

seen to be at the lower border of the ramus, inclosed in a large cyst.

Teeth which have been devitalized for a long time often show an enlarged condition at their apices, which is known as exostosis. This enlargement is due to hypercementosis caused by the continued chronic inflammation, which stimulates the cementoblasts to form new layers of

FIG. 5.

cement at the part where the lesion occurs. Such teeth, especially if located in the lower jaw, are difficult to extract, and, as a rule can only be removed after a considerable portion of the alveolar process has been dissected away. There are many reasons why it is advantageous to diagnose such conditions by means of roentgenograms. Preparation can be

FIG. 6.

made, *e.g.*, for an operation that requires more instrumentation than a simple extraction, and there is no danger of the patient getting the idea, as sometimes happens, that the operator fractured the tooth on account of unskillfulness, and then had to resort to a long, tedious procedure, which may make him resentful and unwilling to pay an adequate fee.

The operator is also able to choose an anesthetic which is sufficiently lasting.

The first molars with exostosed roots shown in Figs. 2 and 3, the curved roots of the first molar in Fig. 4, and of the bicuspid in Fig. 5, as well as the badly exostosed first bicuspid in Fig. 6, are cases in which the roentgenogram disclosed the fact that the teeth could not be removed without dissecting away the alveolar process.

BLIND ABSCESSES.

The development of the roentgen ray for dentistry made us realize the condi-

FIG. 7.

tions which may be caused by devitalized teeth in the alveolar process and the jaws. The bone surrounding the roots of such teeth is almost always more or less involved and displaced by granulation tissue of infectious nature. This loss of bone shows as a dark area in the roentgenogram, and it is important to realize that such conditions start and may grow rapidly worse without giving any discomfort to the patient or obvious signs of disease. If teeth are extracted without considering these infections of the bone, the condition may continue to exist in the mouth for many years and be a source from which absorption of pus may occur. It is therefore imperative to see

whether the tooth to be extracted is complicated by the condition commonly called a granuloma or blind abscess, and to find out its size and its relation to important adjacent structures, such as the mandibular canal or the antrum of Highmore.

of all such cases are due to dental infection. Chronic maxillary sinusitis often occurs without any alarming symptoms in a manner similar to that in which blind abscesses or granulomata are formed, and it is common for such conditions to be discovered during a merely

FIG. 8.

Fig. 7 shows a case where the blind abscess is quite extensive, and the necessity of properly opening into such an area and curetting it is self-evident.

MAXILLARY SINUSITIS CAUSED BY CONDITIONS OF THE TEETH.

Maxillary sinusitis, in its acute suppurative, or chronic form, is frequently caused by infections from the teeth. According to Brophy, about 75 per cent.

routine examination. This brings out the importance of determining the condition of the maxillary sinuses when large abscesses are found on the upper bicuspid and molar teeth. On the other hand, when a diseased antrum is found, one should always take roentgenograms of the teeth to see if the trouble is associated with disease conditions of these organs. A few illustrative cases are shown in Figs. 8, 9, 10, 11, and 12.

(Fig. 8.) Mr. W. C. had pain in

the zygomatic and infra-orbital regions with discharge from the right nostril. A frontal roentgen plate showed radiopacity of the right antrum. The cause was ascertained by a film, Fig. 9, which showed radiolucent areas on two roots of the upper first molar, indicating abscesses.

FIG. 9.

(Fig. 10.) Miss A. P. was in poor health, and was referred by her dentist for extraction of the upper left molar. After extraction of the tooth a probe could be passed into the antrum. The previously taken films of the teeth showed a large radiolucent area on the roots of the upper first molar. The second molar

FIG. 10.

was devitalized also. A frontal plate taken immediately after the extraction showed radiopacity of the left maxillary sinus and a cyst of the right maxillary sinus.

(Fig. 11.) Miss M. L. had been in a run-down condition for some time and had been under a physician's care, but did not improve. The roentgenographic examination of the teeth showed indications of many pus pockets and abscesses in the right upper jaw. The condition of her antrum was questioned, and a

frontal plate showed it to be involved on that side.

FIG. 11.

FIG. 12.

(Fig. 12.) Mrs. F. K. complained of severe pain in the head. Films of the teeth showed abscesses around the upper first molar, which was the abutment of a bridge. Involvement of the maxillary sinuses seemed possible, and a frontal plate proved this to be the case.

PERIODONTAL OR RADICULAR CYSTS.

This type of cyst is of inflammatory nature, and has its origin in an epitheliated granuloma or blind abscess. Exudates which accumulate on the inside cause an expansion of the cyst, which grows at the expense of the bone. They may grow enormously and are, as a rule, associated with a devitalized tooth. At times, however, we find cases where the cyst continues to grow in the jaw independently after the extraction of the tooth. Such a case is shown in Fig. 13. The patient remembered that he had had an abscessed tooth on that side extracted about sixteen years before, which must have been the first molar, as this was the only tooth absent. The roentgenogram

shows that the tip of one of the roots was left in the jaw and apparently also the abscess sac, which grew into an extremely large cyst. When operating I found the contents of the cyst to be under pressure, and a great deal of pus escaped after the first opening was made to the bone. This case is interesting also from the standpoint of the patient's health having been very poor on account

taken, with the following result: Hemoglobin, 93 per cent.; leucocytes, 6000; red count, 5,800,000.

DENTIGEROUS OR FOLLICULAR CYSTS.

Such cysts are not of inflammatory nature, but are of embryonic origin, developing from the tooth follicle of an unerupted impacted or misplaced tooth

FIG. 13.

of the condition. He had had some palpitation and dyspnea, and was evidently very anemic. He had been undergoing treatment for about a year when he broke down from nervous collapse. Before the operation the blood count was as follows: Hemoglobin, 85 per cent.; leucocytes, 7000; red count, 5,120,000. One week after the operation his physician reported the count to be—Hemoglobin, 92 per cent.; red count, 5,500,000. Six months later his blood count was again

or tooth germ, and they may contain one or many elementary teeth or well-formed tooth masses. They also grow to tremendous size, and the roentgen picture is one of the best means of making a differential diagnosis. Such a case is seen in Figs. 1 and 14 (shown by courtesy of Dr. Halsey B. Loder). The patient, a boy twelve years of age, had a swelling on the right side of his face. This was confined to the ascending ramus of the jaw, and had been noticed

for nine months, there being also a slight amount of pain. The roentgen picture shows a well-formed cyst containing a number of defined teeth and small foreign bodies, which, being of

general practitioner is usually the first to be consulted by the patient. I refer to the making of a diagnosis and the selection of the anesthetic, a discussion of which I thought could be made clear in

FIG. 14.

about the same radiopacity as the teeth, were taken to be indefinite tooth particles.

It was my aim in preparing this paper not to go into the details of the technique of administering anesthetics and performing surgical operations in the mouth, but rather to discuss some features of oral surgery about which the

no better way than by showing these roentgen pictures of some practical cases which have come under my observation.

The Presence of Taste Fibers in the Lingual Nerve.

By ISADOR H. CORIAT, M.D., Boston, Mass.

(From the Surgical Department of the Forsyth Dental Infirmary for Children.)

THE question as to which nerve subserves the sense of taste in the anterior portion of the tongue has been one of the most contested problems in nerve physiology. Experimental and anatomical data leave no doubt that the posterior portion of the tongue receives its peripheral receptors of taste from the glosso-pharyngeal nerve. For the anterior portion, however, opinions have been divided between the lingual branch of the fifth nerve and the chorda tympani.

The mucous membrane of the tongue is innervated not only with nerve endings subserving the sensations of touch, pain, and temperature, but likewise with nerve fibers which pass directly to the specialized groups of taste buds, which may be termed, according to Sherrington, peripheral chemo-receptors.

Physiologists are not in accord on the subject of the innervation of the anterior portion of the tongue by the nerves of taste. Tigerstedt leaves the question open, Haycraft in Schaefer's Physiology states that the taste fibers from the lingual nerve pass into the chorda tympani on their way to the brain. The conception that the taste fibers reach the brain exclusively by the fifth nerve roots was held long ago by Erb, and later strongly advocated by Gowers and Turner. On the contrary, other physiologists (Howell, Herrick) claim that the taste fibers are merely carried in the lingual nerve, and brought to it through the chorda tympani nerve.

It has further been pointed out that the loss of taste after operations on the Gasserian ganglion is merely temporary, an incidental result, due probably to

post-operative degeneration and swelling of the fibers of the lingual nerve, which affects the conductivity of the intermingled fibers of the chorda tympani. It will be shown later, however, that this loss of taste is permanent and that, coincident with this, there is complete loss of all sensation over the distribution of the lingual nerve.

Most of the data on the nervous pathways and the peripheral receptors for taste on the anterior portion of the tongue have been derived from these operations on the Gasserian ganglion, the end-results of which operations as affecting the sense of taste have been severely criticized as complicating the evidence, on the ground that such operations produce only temporary changes, due probably to post-operative degeneration and swelling of the nerve fibers, which affects the continuity of the nervous pathways and consequently affects the peripheral chemo-receptors for taste. In the experiments here detailed such post-operative injury was avoided, partly because only the mandibular nerve was injected with novocain, and partly because an isotonic solution was used (Ringer's solution). Furthermore, the tests were made on children, in whom there is a greater and more accurate sense of taste than in adults.

According to Cushing,* whose conclusions are mainly derived from extirpation of the Gasserian ganglion, the taste fibers for the anterior two-thirds

* Harvey Cushing: "The Taste Fibers and Their Independence of the Nervus Trigemini," *Johns Hopkins Hosp. Bulletin*, vol. xiv.

of the tongue are independent of the nervus trigeminus, since the perception of taste was never found to be completely and permanently lost after removal of the Gasserian ganglion. He admits, however, that there may be a temporary loss of taste over this area, due to mechanical or toxic disturbances from degeneration of the lingual nerve. After operations on the Gasserian ganglion taste was always unaffected on the posterior portion of the tongue. This latter observation is in harmony with my observations after mandibular injections with novocain in isotonic solution. Krause and other observers, however, have found a complete and permanent loss of taste on the anterior two-thirds of the tongue after operations on the Gasserian ganglion.

That the sense of taste may be completely and permanently lost on the anterior two-thirds of the tongue, but preserved on the posterior third (because the latter is supplied by the glosso-pharyngeal nerve) for a long period after extirpation of the Gasserian ganglion is shown by the following personal observations:

A woman, fifty-seven years of age, had been operated for severe trigeminal neuralgia of six years' duration. The entire right Gasserian ganglion was removed. The sensory examination three and one-half years after the operation revealed the following: The entire right side of the face, lips, and mucous membrane of the mouth and tongue, with the exception of the posterior third of the latter, was completely analgesic and anesthetic. The right anterior two-thirds of the tongue showed no sensation to touch or pain, while taste was completely lost for salt and acid on this portion of the tongue. On the left anterior two-thirds of the tongue, as well as the entire posterior third, taste and sensation were normal. Here it will be noted that the loss of taste had persisted, although more than three years had elapsed since the operation.

The chief criticism that must be directed toward the theory that the distribution of the taste fibers is in the

anterior two-thirds of the tongue is that the deductions are based on the effects of severe operations on the Gasserian ganglion, or on the more or less indefinite tests for taste in the course of examinations for peripheral facial paralysis in which it was felt that the chorda tympani was involved. In none of these latter cases was taste completely obliterated in the anterior two-thirds of the tongue. At the most, the perception of taste was merely diminished.

It was felt that if an exact and definite physiologic experiment could be devised, such an experiment would serve to clear up the much-discussed question of the exact nerve which subserves taste on the anterior portion of the tongue. Fortunately, such an opportunity was offered by studies carried out at the Forsyth Dental Infirmary for Children.

All the subjects observed were children between the ages of ten and sixteen years. In children, as is well known, the acuity of taste is more pronounced than in adults. These children came to the Infirmary for the extraction of teeth under local anesthesia by what is known as mandibular injection. The local anesthetic used was a 1 per cent. solution of novocain in isotonic normal salt solution with adrenalin. The injections were made in all cases at the inferior dental foramen, producing anesthesia of the area innervated by the inferior dental nerve and the inferior dental plexus. In all the cases some of the injected fluid infiltrated into the lingual nerve, and there followed also a complete analgesia and anesthesia of the anterior two-thirds of the tongue on the side of the injection, with a complete loss of taste.

Sensitiveness to touch was tested with cotton or with Von Frey's hair esthesiometer, to pain with a sharp point, and to temperature with small test tubes, while the sense of taste was tested with sweet, sour, bitter, and salt placed on small pellets of cotton.

In these mandibular injections the lingual nerve is involved probably by a branch of the inferior alveolar nerve. This branch of the inferior alveolar

nerve joins the lingual nerve shortly above the inferior dental foramen and thus produces sensory disturbances in the tongue. In none of these injections was the mouth dry on the injected side, because the chorda tympani was not involved, although it is intimately related to the lingual nerve. A blocking of the chorda tympani by the novocain would have the same effect as atropin, particularly since the isotonic solution used contained adrenalin, which would stop the secretion of saliva by constricting the bloodvessels of the salivary glands. The local anesthetic was injected into the inferior dental foramen, and not into the lingual nerve, therefore the sensory disturbances which occurred in the distribution of the lingual nerve were due to infiltration and not to direct injection.

Why, then, after severe operations on the Gasserian ganglion or following mandibular injections, is not taste from the chorda fibers preserved, if there exists a separate sensory pathway by way of the chorda tympani? The reply to this question would be that the taste is absent because the great mass of taste perceptions is conveyed by the lingual nerve together with the impulses for pain, touch, and temperature. Even if all sensation in the lingual nerve were blocked, taste would not be affected if the lingual nerve did not carry taste fibers, because there would be a selective sensory transmission if the two pathways were distinct, that is, taste sensation would be completely preserved if the chorda tympani alone carried taste fibers, even though the lingual nerve were blocked and rendered completely anesthetic. If taste fibers ran exclusively in the chorda tympani, there would be a dissociation of sensation (preservation of taste with loss of sense of touch and pain) after mandibular injection, like the dissociated anesthesia in syringomyelia or the selective sensory regeneration of nerve fibers.

Without entering into the details of the individual experiments, they may be summarized as follows: In all, twenty-one observations were made on children

between the ages of ten and sixteen years. Seven of these were left mandibular injections, six right mandibular injections, and eight double mandibular injections. In all these cases, on the anterior two-thirds of the tongue, either on the right or left side or on both sides, according to the nature of the mandibular injection, there was a complete loss of sensation to touch, pain, and temperature. In every case likewise, there was a complete loss of taste for sweet, sour, and salty objects over the area of the tongue where the other sensations were lacking. In each case, fifteen minutes were allowed to elapse in order that the local anesthetic might reach its full point of intensity. In some of the observations, the anterior two-thirds of the tongue would sometimes show only a diminished sensation for touch and pain, while in this same area taste would be completely lost.

Observations such as these demonstrated that the taste fibers become blocked before the fibers for touch and pain—first, because the former are more highly differentiated, and second, because the lingual nerve must contain taste fibers; otherwise no diminution of taste sensation would have taken place over the distribution of the lingual nerve. This is in harmony with my observations on selective sensory regeneration, in which it was demonstrated that the fibers for light touch are regenerated later than the fibers for pain, because they are more highly specialized and differentiated.* In none of the cases was taste or sensation disturbed on the posterior portion of the tongue.

In one experiment the subject was able to distinguish salt slightly, but unable to perceive sweet. This was probably due to the persistence of special neurons which subserve the function of tasting salt. There was temporary blocking of the "sweet" peripheral receptors—

* See my papers on "Selective Sensory Regeneration in an Ulnar Nerve Lesion," *Journ. A. M. A.*, February 5, 1916, and "The Sensory Evidence of Nerve Regeneration," *Boston Med. and Surg. Journal*, February 8, 1917.

a sort of selective apparatus for different taste qualities, the same as the selective sensory apparatus in the skin (Von Frey, Head, Coriat). Frankl-Hochwart has also pointed out that there may be selective receptors for different taste qualities on the tongue, an observation that is confirmed by one of our experiments.

To summarize, as the result of isolated

mandibular injections with novocain for the extraction of teeth, which is in the nature of an exact physiological experiment, it was found that the fibers for taste in the anterior portion of the tongue pass through the lingual nerve, at least in its peripheral portion, before they join the chorda tympani.

416 MARLBOROUGH ST.

The Relation of the Surgeon and the Dentist in Face and Jaw Injuries.

By HERBERT L. WHEELER, D.D.S., New York, N. Y.

(Read before the Northeastern Dental Association, at its annual meeting, Worcester, Mass., September 26-28, 1917.)

THE value of the dentist and oral surgeon in caring for the wounds of the face and jaws of combatants in the present world-war can scarcely be estimated. The results of the attempts at restoration of mutilated faces, in which dentists co-operated with the surgeon, were so satisfactory that the people of all the allied countries immediately appreciated it, and at once gave the proper credit to the dentist as well as the surgeon. The plastic and oral surgeon and dentist have achieved such results that the work done by them in co-operation will always stand out as one of the advances over the past brought out during this war. Intelligent and fairminded men in both branches of medicine, surgery and dentistry, rejoice at the increased usefulness of the service of our profession to humanity. The work of this kind done at the American Ambulance at Neuilly and at many other points in France by American, French, and English dentists and oral surgeons has begun a new era in the requirements that will be made henceforth upon the dental profession. Such men as Drs.

George B. Hayes, William Davenport, V. H. Kazanjian, Frey, Villain, and many others, have shown that dentistry is something more than mechanics. They have demonstrated that the dental profession does contain men who can rise to the occasion, and meet the responsibilities of any reasonable emergency. They have done more; they have shown that dentistry has a mission quite as dignified and useful as its sister specialties of the medical profession. Not but what we, as a profession, have appreciated this, but the public have not always done so.

INCREASED RESPONSIBILITIES OF THE DENTIST.

This new appreciation, however, besides giving us a sense of satisfaction, carries with it increased responsibilities. Will the members of the profession rise to the occasion and meet the requirements? Only a few have done so thus far. I have faith, however, that we shall "make good." It is the object of this essay to point out in some small measure some things in which we need to develop

greater efficiency before we can measure up to the best surgical standards of the present day.

The work of the dentist is of such a character as to develop the very highest finger ability. The dentally trained oral surgeon should have the greatest technical ability. Finger dexterity, however, is of no value unless the mind that directs the fingers has a thorough knowledge of the fundamentals. We must know the structure, the muscles that produce movement, the arteries and veins that supply nourishment and carry off waste, and the nerves that direct movement. We must know the growth, development, and cellular tissue of all these, and not only know them, but remember them. How would the plastic surgeon know where best to attach new tissues or place sutures, if he had not a thorough acquaintance with the tissues with which he is dealing?

As far as I am able to judge by my relations with hospitals and institutions, from such fracture cases as I have seen handled by the surgical wards it is evident that the practitioner of medicine and surgery expects the conditions of the mouth to be cared for by dentists, and acting on this hypothesis, the majority of them pay very little attention to mouth conditions except those of malignant growths or benign tumors. Their sole recourse in case of fractured mandibles or dislocations of the maxillary bone is usually the Barton bandage, or some other method of that type.

I believe that most dental colleges today are giving very satisfactory courses in oral surgery, and that a knowledge of fractures of the mandible and maxillary bones, and their treatment, is pretty carefully taught, and if a student leaves the average institution without a fundamental knowledge upon this subject it is largely due to his own neglect. In treating traumatisms of any kind, a competent dentist should be capable of doing the necessary and intelligent thing. In the injuries and mutilations, however, that occur on the fighting front in Europe, the injuries received are almost never confined to a simple fracture.

They are practically always compound or comminuted fractures, plus serious lesions of the soft tissues of the face and mouth, and sometimes other portions of the head and neck.

NECESSITY OF CO-OPERATION BETWEEN THE ORAL SURGEON AND OTHER SPECIALISTS.

One reason why the American Face and Jaw Hospital, which started off so nicely, was bound to fail, as it has, was its attempt to handle exclusively face and jaw cases. Theoretically this plan seemed good, and promised well. Practically, the Huns have never been considerate enough to use explosives and death-dealing missiles that would injure in one spot only, and a man might be brought to the hospital not only with a seriously mutilated face and jaw, but with an arm or a leg gone, or serious wounds of the body, as I have seen, and a hospital without all the equipment and staff of resident physicians and dentists to take care of these needs was doomed to failure from the start, though this did not appear to those who so conscientiously gave of their time and money to establish the institution.

You will see, then, that it is necessary to have all the injuries treated simultaneously. You will also know, if you are acquainted with the training of the dental profession, that few if any dentists are capable of attending to the flesh wounds or doing plastic surgery in conjunction with their bone and fracture work. How many men, do you think, in an audience composed of dentists, if they were asked what material was most desirable for suturing wounds, could answer immediately? How many could tell you how long sutures should be retained before being removed, and in what cases they were not to be removed at all? How many could tell by observation which tissues had best be sutured, and which are best brought into proximity in some other way? In fact, how many dentists could carry on a treatment outside of the vestibule of the mouth? I think you will agree with me that there

are very few. Hence the surgeon, the man accustomed to dealing with wounds of the tissues, is a necessity, and as soft tissues heal and disintegrate more rapidly than bony structure, it is evident that it is essential that the plastic surgeon shall have direction of the case until the soft tissues are healed or sufficiently attached to insure safety from a reopening of the wound.

Furthermore, how many dentists do you think can give you accurately the blood supply of the face and jaw, and the nerve supply, and tell you whence it arises, and could go at once unerringly to the place for proper ligation in case serious hemorrhage should occur? Lack of such knowledge, however, does not reflect upon the ability of the dentists to understand thoroughly the tissues of the vestibule of the body, the mouth, and be able to diagnose dislocations, fractures, infections, necrosis, caries, neoplasms, and traumatic injuries of all kinds, plus a knowledge of the necessary mechanical appliances—one might say, engineering equipment. To replace lost parts is a task worthy of a well-equipped surgeon, therefore the dentist need not apologize for being unable to take up instantly plastic work and carry it on. He should, however, have an appreciation of the distinction between the necessity for quick action and healing by first intention of soft tissues and the necessary preparation for mechanical artificial substitution, and should work harmoniously and in sympathy always with the plastic surgeon.

The difficulties of plastic work, especially when it requires grafting of new and foreign tissue on a part, are such that the nourishment, care, and activity of the patient must all be carefully considered; therefore again the plastic surgeon is entitled to direction of the case. This also obtains in bone-grafting, and if the oral surgeon attends to the bone-grafting, the same privilege should be accorded to him. In other words, the direction of those forces which make for a proper upbuilding of the patient's strength and feeble powers, which must be considered in any recuperation from

injury or disease, must go hand in hand with a knowledge of the technical ability which seeks to repair or replace.

It is unquestionably the function, then, of the general surgeon, who is undoubtedly the best qualified as a specialist in plastic surgery, to have the direction, care, and control of these seriously mutilated face cases, as it is the duty of the oral surgeon to care for fractures or loss of the bony tissue. If the best results are to be obtained they must work in unity. Even the man who attends to the extraction or replacement of artificial teeth must become a part of the harmonious whole and must consider the condition of the osseous and soft tissues before attempting to insert artificial substitutes or treat disease conditions of the alveolar process or roots of teeth.

DENTISTRY AS A SEPARATE DEPARTMENT OF THE ARMY.

It would seem, then, that the idea of some men that dentistry should have a department connected with the army exclusively its own is not based upon a thorough knowledge and understanding of the requirements in face and jaw wounds. I sometimes wonder if some of those who shout so loudly for the independence of the dentists in these matters have not an idea that you can send your poor wounded, mutilated, nerve-racked soldier about from pillar to post, as some dentists do their patients in an attempt to confine themselves to what they are pleased to call a dental specialty.

You may know that the United States Government, through the Surgeon-general's Office, is contemplating, and I think has already organized some *head* units. The government has at no time attempted to create a head unit exclusively of surgeons or exclusively of dentists. It has placed a number of both oral surgeons and dentists in each head unit, guided evidently by the intelligent conception that in order to get the best results and make the most complete cure of the unfortunate victims of this war they must all work together. In this I am quite sure that you will all agree

with me that the Surgeon-general's Office has shown marked ability to appreciate the situation. You will also find in it, I think, cause to strengthen our belief that dentistry is and must be a branch of the healing art, or we are mere mechanics.

If we are mere mechanics or beauty doctors, our position is with the barber, the manicurist, and the chiropodist. If we are followers of the healing art, we must of necessity have a thorough knowledge of the histological and anatomical structure of the tissues and organs we have to deal with. We must have a thorough knowledge of the difference between normal and pathological conditions of these tissues, and must be able to differentiate, that is, we must be diagnosticians. We must also understand the effects of the presence of foreign substances or invasions of injurious bacteria; we must know our blood supply and our nerve supply, and the effects of injury, also the effects of remedies. A knowledge of these things is what is being given in good dental colleges today. A recognition by the dental profession that the teaching on these subjects was not sufficient brought about the four-year course in dental colleges which became operative at the opening of the present session of all the dental colleges of this country;—and even with a four-year course the time is all too short to impress upon young and often thoughtless students the necessary details to supply them with a working knowledge of the tissues they are expected to care for.

It may interest you to hear from me some comments on my experience as an examiner of applicants for commission in the dental section of the Officers Reserve corps of the United States army. In New York we have examined upward of six hundred men who have applied for commissions, and our examination has been a fair one. It has been based upon a desire to give the Government that which it needed, expert service as dental and oral surgeons, and to be fair to the applicants without regard to race, creed, or color. No man has come before our board who has not had to undergo

an examination as to his knowledge of fundamentals and as to his mental and technical equipment to serve his government in the way he aspired to do.

We have found that in a majority of cases dentists who have been more than a year away from their alma mater are seldom able to answer questions as to the blood and nerve supply of the face and jaw in detail. We have found less often, but all too often, that they did not know the muscular attachments or even the muscles of mastication. We have found often that men who claimed to be specialists in extracting did not know which was the thinnest plate on the alveolar process of the maxillary bone or the mandible, a thing that any man with experience in extracting could not help but observe.

Some men having listened to the answers that we have listened to since last May would have unhesitatingly and unqualifiedly condemned our teaching institutions in dentistry. Let me tell you that it has made no difference where a man was graduated, whether from the most famous universities in the country or the most obscure private colleges, the knowledge of fundamentals becomes rapidly rusty—in many cases soon after termination of the required course in the dental college. I am convinced that it is not due to lack of teaching. I am sure that the quality and quantity of teaching upon this subject in most dental colleges is sufficient to well equip a man, if he desires to know and to remember the subject. The difficulty, I am satisfied from questioning and cross-questioning, is with the individual.

NECESSITY OF MORE INTEREST IN PROSTHETIC DENTISTRY.

There is scarcely a teacher in a dental institution in the country who will not agree with me when I say that the ambition of the average student who enters the dental college is not sufficiently great for him to appreciate the necessity of an intimate knowledge of the tissues he must work upon. They are all desirous of putting in gold fillings, gold inlays,

filling root-canals, and vying with each other in putting the finest polish on their fillings, and perhaps doing the most beautiful plastic work or making the most natural-appearing porcelain substitutes. Occasionally you find one who is desirous of knowing and understanding prosthetic work, but the majority of them will do everything possible to put in most of their time in the operating department and at the operating chair. They will only study sufficiently to enable them to pass the examinations; they look upon anatomy, physiology, histology, materia medica, chemistry, therapeutics, etc., as studies which they care nothing about, except to be able to answer some set questions that will be presented to them at the end of each term, and enable them eventually to secure the coveted diploma. They seem not to be able to reason from cause to effect or to know that a thorough knowledge of the groundwork is more desirable than influence or clever advertising.

I know not if anyone is to blame for this; probably not, only weak human nature. Even prosthetic dentistry is evaded as far as possible. They say, "Well, I can get that done outside at the dental laboratory. Why bother with that?" As I know something about the prosthetic work in dental colleges and as I lecture upon that subject in one institution in this country, I have endeavored to impress upon the minds of the young men the fact that a thorough knowledge of the mouth, its histology, its anatomy, its physiology or function, the mechanical principles of the action of the mandible, and an ability to restore lost parts by artificial substitutes that accomplish the function which the original or lost part accomplished is a greater achievement than all the operative dentistry in the world, and I think mouth conditions resulting from the present war have borne out my opinion on that subject.

NEED OF MORE PROSTHETIC DENTISTS IN THE ARMY.

The United States Government today has more dentists commissioned than it

will need if the war is continued three years, but it is begging and imploring men with only a little knowledge of oral surgery and a genius for prosthetic restoration to accept commissions and serve their country.

What is to be the remedy that will give the dentist a proper view of his responsibilities, and teach him unerringly the requirements that he must have to attain his desire to be of service to his community as a professional man? I think the remedy must lie, first, possibly in a more distinct and plain statement of the true situation, beginning with his freshman year, and of the necessity for deep-rooted knowledge of these subjects, not surface information to be forgotten as soon as his state board examinations are over. I believe, next, that a closer and more intimate relationship must be cultivated between the dental specialty and other specialties of medicine. They must realize that each forms a part of a whole, and that each is as dignified and as worthy of respect as the other as long as each does its work well—and by well, I mean that the results shall evidence a complete knowledge of the subject of which they assume to be masters. Often the training of men in this field seems to detract from their ambition to do mechanical work. This is unfortunate, for to be of any great service in this mouth and jaw work, a dentist must not only be an oral surgeon, but must be a good prosthetic dentist. And while it is not required and not necessary that he should mechanically make and shape parts in order to have them made and shaped as he wishes, he must be master of the situation and thoroughly capable of doing so in case of necessity.

To sum up the situation, then, it is necessary that the general surgeon work in co-operation with the mouth surgeon and the prosthetic dentist to properly handle these mutilated cases that arise from face and jaw wounds at the battle front. The oral surgeon and the technically competent mechanical dentist are also essential. Neither one can carry to completion the necessary work without

the assistance of the other; nor can one be in full sympathy with the other without a proper understanding of the responsibilities and work of the other. Therefore not only should the oral surgeon and the prosthetic dentist have a thorough knowledge of the fundamentals involved in the entire range of injuries that occur in the face and jaws, but the general surgeon should also have a knowledge of the requirements of the oral surgeon and prosthetic dentist. The difficulties that sometimes arise in this combination are not always entirely the fault of one specialty. Frequently narrowness on the part of all is responsible for them, and most often a willingness to work so as to be of assistance

to the other would overcome the difficulties.

Let us keep in mind, then, that the primary cause for all of this work at the present time, dental departments in base hospitals and head units for base hospitals, is to bring back to normal condition, as far as possible, the man who has been frightfully mutilated and injured because of his patriotic service to his country. Let us ignore what we conceive to be personal rights and dignity, and forget all in an endeavor to help the man who has sacrificed all.

Method of Taking Modeling Compound Impressions with the Mouth Closed and Under Normal Biting Strain.

By JOHN H. DREXLER, D.D.S., Philadelphia, Pa.

(Read before the Academy of Stomatology of Philadelphia, November 27, 1917.)

MY object in coming before you with this paper is to give to you in a simple and effective manner the method of taking impressions with the mouth closed, and under normal biting stress.

A few moments of careful thought on this subject will convince one that the usual method of taking impressions is decidedly wrong when dealing with soft or movable tissue, as also is the idea that an air-chamber in the center of an artificial denture is essential to secure it against the strain of mastication.

The greatest comfort in a denture can only be obtained when you have equalized the bearing on the soft and hard tissues alike, while they are in their working position. Hence this equalization must be done in the impression with the mouth closed and under normal biting stress;

and in order that there may be no doubt about the finished product, the so-called impression must be the exact model of the proposed denture, as far as the height of the rim, thickness of the edges, and length of the plate in the rear are concerned.

In preparing to take an impression by this method, we first examine the mouth, both opened and closed, by passing the index finger along the buccal and labial region of the ridge, also along the posterior portion of the vault, to get an idea of the height of the rim and the length of the proposed denture by noting the strength and position of the muscles and soft tissues in action. We should also note particularly the amount and area of soft tissue in the posterior third of the vault.

We next select a suitable impression

tray. The tray must fit the vault exactly at the rear edge, and the buccal and labial borders of the ridge approximately, allowing about one-eighth of an inch on each side to accommodate the modeling compound.

The buccal and labial edges of the tray must be trimmed one-eighth of an inch short of the muscular attachments to allow for muscle trim. When the ridge is hard in front, the tray must be trimmed to the exact length of the proposed plate, that is, within one-sixteenth of an inch of the edge of the vibrating soft tissue. If the ridge be soft in front, then the tray must be fitted to within one-eighth of an inch or less of the full length of the proposed plate.

The handle of the tray is bent in such a manner as not to interfere with the lip or with the finger when placed on the rear third of the tray. If the patient is subject to nausea, the posterior edge of the tray must be embedded sufficiently to eliminate vibration of the soft tissues, and the tray in this case should be the exact length of the plate to be.

With a mental photograph of the mouth and a tray properly fitted and dried, we next turn our attention to the modeling compound.

PREPARATION OF THE MODELING COMPOUND.

The only reliable heater for heating modeling compound is an electric heater which allows three grades of heat—low, medium, and high. With this apparatus the compound can be made extremely soft without boiling, and an even temperature may be maintained indefinitely. Modeling compound should never be boiled.

We next take from our heating-pan a small portion of compound, and with moistened fingers form it into a ball. Heat one side in the flame until it sizzles, and place it on the tray with the heated portion next to the tray, and after again moistening the fingers, quickly shape the soft compound into a mound in the center of the tray with a depression all along where the alveolar

ridge will come, and with a relatively high ridge to go up under the lip and cheek. The compound should not be allowed to extend quite to the posterior border of the tray.

We now heat the entire impression surface of the compound over a Bunsen flame, so that the surface may be rendered softer than the underlying portion, and after dipping the entire impression material into hot water we are ready to take our first impression. Right here let me say that it is essential that compound heated by dry heat should always be dipped into hot water before being placed in the mouth. This will prevent sticking to the mucous membrane, and incidentally possibly save your patient from a severe burn.

TECHNIQUE OF TAKING THE IMPRESSION.

The object of the first impression is to fit the compound to the roof of the mouth only, and to get the height of the rim.

The tray is passed into the mouth and pressed about half-way home with a wavelike side-to-side motion, and centered. The compound on the buccal and labial surfaces is pressed upward and against the ridge by using the finger. We now instruct the patient to give the motion to the lip and cheek, first as in hearty laughing, then as in whistling, while we gently push the tray home with the index finger under the rear third; then, while the material is still moldable, massage in the region of the tray to make surplus compound flow underneath. In massaging, the first motion is upward, and the second straight inward and forward. When thoroughly hard remove the impression, and place in a pan of cold water.

The margins of the impression, as it first comes from the mouth, are generally thick enough to distend the tissues of the cheeks and lips, a condition which must be remedied.

We next trim the buccal and labial margins until they are of the thickness desired in the finished denture to give the patient's face the desired expression. Care should be taken not to alter the

form of the margins or to break the compound. If the compound is broken in trimming, no effort should be made to repair it until after the bite is taken, as any attempt to repair it before that stage is reached usually results in spoiling the impression. If the posterior margin of the impression cup is exposed in taking the impression, it should be bent backward out of contact with the tissues. The exposed area will later be covered with compound.

TAKING THE BITE.

The taking of the bite, which is the next step, is of vital importance, and differs slightly in technique for a case requiring a full upper and lower denture from that for a case requiring a single denture with the upper or lower teeth in place.

Owing to the limited time, I am compelled to confine my paper to one class; we shall therefore consider taking the bite for a full upper denture with the lower teeth in place.

Before attempting to complete the impression, the biting pressure on both sides of the plate should be equalized. This is done by rolling out a piece of compound, and after passing it through the flame, sticking it to the under surface of the tray. Quickly shape it to approximate the lower teeth, heat until it is very soft, dip into hot water, and place in the mouth. The patient is now requested to bring the lips together until they assume the rest position. At this point let me emphasize the necessity of having the compound so soft that the patient does not notice any pressure when closing. If the compound be heated unevenly, the muscles straining on one side or the other to overcome this resistance will produce a false bite.

The bite is now removed and all surplus trimmed off, leaving only the very slight dents indicating the cusps of the lower teeth. The biting surface is again warmed over the flame equally until the heat has penetrated about one-eighth of an inch in the molar region and one-sixteenth of an inch in the region of the

six anterior teeth. The bite is placed in the mouth being sure that the lower teeth bite into their original markings in the compound, and the patient instructed to close down firm and hold the jaws in the rest position.

Up to this point we have produced something which we know will compel the patient to bite in exactly the same way every time we request him to close. This is absolutely necessary in order that we may modify the margins, or, in other words, get the muscle-trim.

MUSCLE TRIMMING.

The finishing or last step in this procedure is accomplished by modifying the margins of the impression to conform to certain portions of the soft tissue under normal biting strain.

The first step is to make sure that the margins are high enough. The experienced operator will be able to detect low places in the margins of the impression at a glance, but the inexperienced cannot do this.

In the first cases one attempts it is well to add compound by heating a stick and building up all along the margins. Quickly insert after heating to see that the bite is correct, and to have the patient perform the laughing and whistling movements while the cheeks are gently massaged.

As soon as the margin is high enough all around and has been muscle-trimmed and massaged, the entire buccal and labial margins should be warmed beside a small flame until the compound is soft enough to permit adaptation by massage, but not soft enough to change its form. The impression should be quickly inserted in the mouth, the patient asked to again make laughing and whistling movements, and the compound massaged to a better adaptation to the buccal and labial tissues.

It is also very important that the upper impression should be adapted to the soft tissues which overlie the posterior part of the hard palate on either side of the median line when these tissues are relaxed.

Impressions taken with the mouth open reproduce these tissues in distended positions. When the mouth is closed they occupy very different positions, and a denture made over a model representing the distended positions may fit them so poorly as to cause nausea. If the denture fits these tissues in their relaxed position it will be stable at all times, and will not cause nausea, no matter how long it may be.

The impression is adapted to the relaxed position of these tissues by adding compound over the entire area which they occupy, and while the compound is very soft, insert the impression into the mouth and have the patient close tight on the bite block, instructing him to swallow two or three times. The tongue is automatically carried to the roof of the mouth during swallowing, and this action drives the soft compound into firm contact with the tissues overlying the posterior portion of the hard palate, and holds it there until it cools.

It may be necessary to add compound in the manner just described two or three times before the added compound blends smoothly with the rest of the palatal surface.

The impression is trimmed to the exact length desired in the finished plate.

the posterior border of the impression warmed, placed in the mouth, and the patient again asked to swallow a few times.

The impression is now removed from the mouth and the buccal margins on each side over the tuberosities warmed deeply, using the side of a small flame so as not to distort its shape; quickly replace in the mouth, and have the patient close with a strong bite. This pressure properly muscle-trims the posterior part of the buccal margins to the movements of the muscles in this region. This trimming is very important, as it prevents a tendency to force the plate forward in biting.

The impression now, to all intents and purposes, is finished, and if the foregoing technique has been followed conscientiously, we should have a good one.

This is merely an outline of the principles that are necessary to be applied in the construction of dentures by which a patient will get efficiency never attained before by those who have been making them by the old method.

[See also *Discussion*, as reported under "Proceedings of Societies," this issue.]

The Effect of Mouth Infections upon the General Health.

By R. W. BUNTING, D.D.S., Ann Arbor, Mich.

(Clinic given at the annual meeting of the Dental Society of the State of New York, held at Rochester, May 10 to 12, 1917.)

IN the presentation of this subject I recognize that there are in the audience at least three classes of practitioners: First, those who have heard of the possibility of mouth infection being a menace to the body as a whole, but do not believe that it is true; second, those who believe it is true but have been so overwhelmed by the possibilities and responsibilities of dental practice in the light of present knowledge that they are uncertain as to the proper procedure in practice; and third, those who have become over-enthusiastic and extreme in their attempt to meet the new situation. In the few minutes which I have to give to the subject I wish to address my remarks more especially to the second group, those conscientious and painstaking operators who are perplexed by the trend of dental literature and teaching regarding dental infections today.

Gentlemen, I shall ask you to turn back with me ten years in dental practice. You will remember that we were busily engaged repairing and replacing teeth as best we could by the then known methods. We little suspected that the work we were doing had any direct effect upon the general health of our patients. In a general way we knew that the proper function of the mouth in mastication was of benefit to the body as a whole, and some of us had a hazy idea that chronic abscesses and pus-laden pockets about pyorrhetic teeth might be injurious, but most of us gave very little thought to such possibilities. Little did we suspect that today we would be called to account for the things

we did in dental practice, and be charged with the responsibility of many and sundry ailments in our patients in places far removed from the mouth.

It was in 1910 that the first real interest was raised in the significance of dental infection by the strong statements of Dr. Hunter, who said that it was the cause of septicemia and heart lesions. A few years later Rosenow found that many systemic conditions, such as affections of the nerves, heart, kidneys, muscles, joints, appendix, and gall-bladder, which had formerly been considered as disease entities, were the result of infection. These infections he found to be specific blood-borne streptococci, and these had an affinity for certain tissues when injected into animals, these tissues being in a large per cent. of cases the same as were affected in the original patient from which the culture was taken. He then sought to determine the avenue by which these infections entered the body, and their source. The portals of entry he found to be in injuries of various sorts, the natural openings of the body, and the sinuses. But of all of these the most common portals of entry proved to be through the tonsils, the nose and its accessory sinuses, and the mouth. In the mouth he found dental abscesses and pyorrhea, the prevailing organism of which was a streptococcus similar to that of certain lesions in the joints, muscles, etc., and these same organisms when injected in animals produced lesions similar to those of the patient from which they were taken.

These experimental studies of Rose-

now have been corroborated by a mass of clinical evidence from such men as Billings, Mayo, Moorehead, Hartzell, Price, and others, who have shown that many such cases give evidence of marked improvement when the oral foci have been cleared up and the primary infection eradicated—all of which has seemingly established beyond question the possibility of oral and tonsillar infections as direct causes of various systemic diseases. Later work has demonstrated the wide distribution of such systemic affections, and revealed an appalling prevalence of oral infections which may be harmful to the general health.

The result has been a widespread concern on the part of the dental profession as a whole in the significance of these findings as regards the proper procedure in everyday practice. Many conscientious operators have been appalled by the evidence at hand, and have been made to lose confidence in the safety of the operations which they have been making. Because of the possibility of infection they fear to devitalize a tooth, they fear the filling of a root-canal, they fear the treatment of an abscess, they fear the crowning of a tooth or the placing of a bridge, the treatment of pyorrhea, and sundry other operations which have been a matter of daily routine for years. They have lost confidence in themselves and their work, and are now seeking to know just what is safe and sane in dentistry.

Such an unsettled and perplexed state of mind is unfortunate unless it leads to a definite course of action which shall be an improvement upon the old ways and clear up the dilemma which now exists. It is therefore worth while to take stock of the things which we really know, and upon them build a procedure which is safe and sane.

In the first place we must recognize the fact that much that has been written and said upon the subject has been tinged with an over-enthusiasm, with the result that frequently a greatly exaggerated view has been given. If the reports obtained in investigations of free clinics and charity hospitals in the great cities

were truly indicative of the condition of the average practice, we might expect that in the past ten years of practice at least fifty per cent. of our patients would be confined to hospitals or would have passed to the great beyond as the result of the dentistry which we have done for them. On the contrary, we have reason to believe that the dental service rendered by hundreds of careful and conscientious operators of the past has not resulted in the crop of direful and disastrous results which have been pictured. Not that we would minimize the significance or importance of dental infections, or the dangers of careless and slovenly dentistry, but we do not believe that any evidence has been shown which has discredited the work of the careful and painstaking operators who have given their best efforts to perfect their dental operations. Such men may have their failures, but their percentage of errors is far less than is depicted by the reports of indifferent and, we might say, criminal dentistry which have been presented as evidence of dental conditions as a whole.

PREVENTIVE DENTISTRY THE DENTIST'S SAFEGUARD.

Our duty as dentists lies in the prevention of infection entering the body through the tissues of the mouth. We find that many pathogenic organisms are common inhabitants of the oral fluids, but that they are kept from the circulation by the mucous membrane which lines the mouth. It is only by breaking down these barriers that infection may gain entrance to the mouth tissues, and thence to the circulation beneath. One vulnerable spot in the mucous membrane is to be found in the openings which are made in it by the eruption of the teeth, and which exist about each tooth as long as it remains in position. Normally, the soft tissues are held tightly about the teeth, but when by injury or irritation this relation is lost, access for infection to the deeper tissues is opened up. By progressive stages the process which we

know as pyorrhea severs the attachment of the tooth and surrounding tissues, producing a sheltered pocket in which organisms may grow and gain access directly to the circulation.

The second most vulnerable point in the mouth is that of teeth which have been attacked by caries; this destroys the pulp, which becomes infected with disease-producing organisms. The infection, after producing a putrefaction of the pulp, may then pass through the apical end of the root, to infect and destroy the tissues in that region by the formation of an abscess.

As these are the two most common and almost sole methods by which dental infection may enter the blood to be a menace to the body as a whole, we are chiefly concerned in pyorrhetic involvement and in devitalized teeth.

THE X-RAY AS AN AID IN DIAGNOSIS.

For information regarding the progress of periodontal infections we have resorted to the use of the radiogram, without which a trustworthy diagnosis cannot be made. But many are making the error of using radiograms as an ultimate means of diagnosis rather than as one of several factors, which it really is. The practice of diagnosing a case from the radiogram alone is untrustworthy and dangerous. Take, for instance, the appearance in the film of a slight rarefaction or minutely abnormal condition at the apex of the root of a tooth. With our present knowledge no one is able to say in all cases whether this is an active infection or a latent one, a scar of an old injury, or *necrotic tissue*. In such a case our procedure should be guided largely by the general health of the patient. If there be no systemic affection and no direct evidence that the tooth is a menace to the individual it may be placed under surveillance, and not molested until such evidence is seen. But in case the patient gives evidence of systemic lesions of an infective nature which might possibly originate in the tooth under question, every effort should be made to clear up

this and all other suspected foci in the mouth, even to the extraction of all such teeth.

Sanity and good judgment must control our diagnosis, rather than radical measures and empiricism. When a patient is referred by the physician as suffering from focal infection, no man can say at once that this infection has its origin in the mouth. Though there may be many abscesses and pyorrhea pockets in evidence, these may all be walled-off by granulations, and the poisonous effects of the infection confined, while an infected tonsil or antrum may be the real focus of the invader. But in any such case it is our duty to completely clear up all dental infection, by treatment, root resection, or extraction if necessary, until we may truthfully say that no focus of infection exists in the mouth. Then, and not until then, have we done our duty. If the patient recovers from his general symptoms we may infer that we have found the cause, but if he does not, search must be made in all of the other avenues by which infection may enter.

EFFORTS TO STANDARDIZE THE OPERATION OF ROOT-CANAL FILLING.

In regard to the filling of root-canals, very commendable advancement has been made in the past few years. Such men as Rhein, Callahan, Best, and Coolidge are seeking to reduce that operation to an exact science, and their teachings should be mastered by every practitioner. When this has been done, no conscientious operator need hesitate to devitalize a fully formed tooth whenever it is necessary to the performance of good dentistry. Such procedure when carefully done is much to be preferred to the overloading of vital pulps with irritating crowns and large inlay restorations which will ultimately cause their degeneration or death.

In pyorrhetic infections it is agreed that the deep and inclosed varieties are the ones to be feared. These are open to two methods of treatment other than extraction. By surgical planing and smoothing of the root the infection may

usually be removed and the tissues caused to heal about the tooth, or the pocket may be eradicated by splitting the gum tissues with a lancet, thus barring the root to the point of healthy attachment. In either case the infective process must be stopped or the tooth removed.

Although some of us may feel that the pendulum of dental opinion is swinging too far in the enthusiasm over dental infection, it still remains that when this pendulum shall come to rest, it will be at a point removed from that at which it rested ten years ago. It will be over

on the side of thoughtful and earnest consideration of dental operations in the light of the knowledge which has been gained. He who shuts his eyes to these possibilities and the evidence which has been offered is deceiving himself, and will soon be pointed out as a menace to his community. We must all perfect ourselves in dental diagnosis in regard to infections; we must learn to fill root-canals, and to treat pyorrhea. When we have done this, we may practice dentistry with joy in our hearts, and with the firm conviction that we are doing a real service to mankind.

The Technique of Making Dental Radiographs.

By LEUMAN M. WAUGH, D.D.S., New York, N. Y.

(Clinic given at the annual meeting of the Dental Society of the State of New York, held at Rochester, May 10 to 12, 1917.)

IT will be my endeavor in the few minutes we shall have together to make clear to you that it is entirely feasible for any practitioner to do his own radiodontia right in his operating room, without seriously disturbing the average standard dental equipment. All that is necessary for us to have is an electric outlet, and the X-ray machine.

There are in the exhibit room several radiodontic outfits, any one of which I believe will give satisfactory service, and the selection may be governed by individual taste. For demonstrating I shall use the type with which I am most familiar, simply as a matter of convenience. Therefore I ask you to accept anything that I shall say as applying to radiodontia and radiodontic equipment in general, and not to any particular make or type of apparatus. Simplicity both of apparatus and technique will be our principal consideration.

First, I desire that we have firmly

fixed in our minds that a radiographic negative is nothing more than a shadow, of which a permanent record is made. The only similarity to a photograph is that the shadow is recorded in the same chemie substance; in no other respect are they similar.

The light and dark areas in a radiographic negative correspond to similar areas of varying density in the structure radiographed. The zones of the structure that are dense resist the passage of the X-rays, producing a relatively light area in the negative, and conversely, the zones of the structure that are not dense permit the passage of the X-rays, resulting in a relatively dark area in the negative. Therefore a radiographic negative can show no more than the variation in the density of the structure, or of opaque substances, such as wires, etc., placed in the structure. A radiograph does not enlarge or magnify.

The technique may, for convenience of

description, be divided into four stages, which are, in the order of procedure—
(1) Seating and position of patient.
(2) Placing of the film and tube. (3) The exposure. (4) Development, fixing, washing, and drying. All these procedures, except placing the film and tube, can be done equally well, with a little instruction, by any average assistant. We shall now consider each stage in detail.

(1) *Seating and position.* The most convenient chair for making a dental radiographic exposure is the one in which the dental operation is being performed. If the rubber dam be in place it need not be removed, although opaque substances, as clamps, matrix retainers, separators, etc., that would cast a shadow in the field to be examined must be taken out. The presence of the dam does not materially lengthen the period of exposure.

(2) *Placing the film and tube.* This is the most important step and can best be done by the operator who is giving the treatment, because of his intimate knowledge of conditions and requirements. This step will take the most time for demonstration, therefore I shall take it up last.

(3) *The exposure.* This should be of definite length; counting is not usually of sufficient accuracy. A stop-watch, or better still, a timing-switch is most advisable, as either leaves the attention free to be centered on the patient.

(4) *Development.* The fingers need not enter the developer. A clip is placed near the edge and the film hung in a vertical position. Most uniform and satisfactory results are obtained by placing the film in the developer for a definite

uniform time, a good working basis being five minutes, although this will vary according to the kind, the strength, and the temperature of the developer, and, what is very important, will depend on the length of exposure. It is best to have an accurate length of exposure and a definite period of development. If the negative comes out too light it will indicate that the exposure was too short, and if too dense, that the exposure was too long. The error can be corrected in developing the second film in the wrapper a longer or shorter time. In the next case the period of exposure can be corrected, so that a negative of proper density can be made in the standard length of time of development. After having been in the developer the desired time, the film is rinsed in water and placed in so-called "hypo" solution for twenty minutes or more, after which it is washed in cool, running water, for forty-five minutes or more, then removed and hung up to dry. This will take from one to two hours, and may be much hastened by placing in the breeze from a fan. A dark room is best. It need not have running water. Any light-tight closet large enough for one person will answer.

By making all factors definite and constant, any average assistant can do equally well all parts except the placing of tube and film, and no one can do this so well as the dentist treating the case, because of his knowledge of individual conditions and requirements.

[Dr. Waugh demonstrated the placing of the tube and film with the aid of a patient.]

576 FIFTH AVE.

The Influence of General Health on Oral Tissue.

By LEROY M. S. MINER, M.D., D.M.D., Boston, Mass.,

ASSISTANT PROFESSOR OF ORAL SURGERY, HARVARD UNIVERSITY.

(Read before the annual meeting of the Northeastern Dental Association, held at Worcester, Mass., September 26-28, 1917.)

THE need for the dentist of a broad training in the fundamentals of medicine, anatomy, physiology, pathology, and chemistry was never more apparent than it is today.

Although there may be persons who believe that general anatomy, including dissection of the extremities, has no place in the dental curriculum, and that physiology of the liver or the pathology of the gastro-intestinal tract has no practical bearing upon the practice of dentistry, yet, to those who have the interests of the dental profession at heart, and who wish to see it developed to its greatest efficiency, two facts must be evident:

First: A constantly increasing demand, many times by the physician himself, for diagnosis and treatment by the dentist of pathological conditions in the mouth which hitherto have been cared for by the physician.

Second: The need of a broader conception of the general field of medicine, if the dentist of tomorrow is going to meet his full responsibility.

The chief factor in bringing about this condition has been the theory of focal infection, and the important part played therein by the teeth. Medical and dental literature have been filled with articles on various phases of this theory. Extravagant claims of remote diseases caused by infected teeth have resulted in a reaction tending to discredit the whole subject. But the work of Goadby, Billings, and many other scientists of recognized standing, together with the mass of clinical evidence accumulating in the prac-

tice of almost every dentist, forces us to believe that the theory must have underlying truth. Hence it follows that dentistry is bound to become a field of broader opportunity than ever before.

However, my own opinion regarding the need of a broader training for dentists is not based solely upon the development of the theory of focal infection. For a long time I have been impressed with the sensitiveness of the oral tissue to changes in that equilibrium of the various structures of the body which we call health. In this paper I wish to present some results of observations made during the last few years which afford a viewpoint entirely opposite to that of infected teeth as factors in producing general disease. I believe that consideration of the influence of general health on oral tissue, as given herein, will furnish additional evidence of the need for a broader medical training in dentistry.

I make no pretense of presenting finished work. Rather am I impressed with the paucity of our knowledge. The general subject is practically untouched, and I feel that here is a fertile field open for research which some of our organizations could take up with advantage to us all.

SYSTEMIC DISTURBANCES REFLECTED IN THE MOUTH.

Here, then, is the fundamental truth underlying this paper: As the tissues of the mouth, both hard and soft, are extremely sensitive to changes in the gen-

eral health, therefore a healthy condition of the tissues of the mouth may be seriously impaired by disturbances in other parts of the body. In other words, while defective teeth undoubtedly may cause systemic disease under certain conditions, it is equally true that general disease may cause pathological conditions in the mouth.

This influence unquestionably begins at an early period in our life history. During infancy, disease or improper feeding, resulting in various degrees of malnutrition, will interfere with the normal development of both teeth and jaws. The pitted incisors and the decalcified first molars which develop during the first two years can usually be traced to one of these causes. Whooping-cough and condensed-milk feeding are in my own experience two conditions to which this type of defective teeth can very frequently be traced. And, of course, in congenital syphilis we have a classic example of injury to teeth due to general disease. In children who have had rickets, early loss of tooth structure is also frequently seen.

Such facts are not new, but their significance has not to my mind been fully appreciated. What more practical way to conserve preventive dentistry or prophylaxis than to place such facts on a scientific basis, amplifying by research the meager knowledge we have gained in clinical observation. In co-operation with other specialists in medicine, especially the pediatrician, the stomatologist has a rare opportunity for service.

INFANTILE SCURVY.

I. To discuss now the subject more concretely, first let me describe a rather common disease with which the dentist should be familiar. I refer to infantile scurvy, or Barlow's disease. Many times, particularly in mild cases, the chief symptoms are retrograde changes in the oral mucous membrane, and for this reason the dentist is consulted first. In this disease the oral mucous membrane is much congested, softened, and deep red in color, occasionally almost black; the

gums bleed easily and show hypertrophy, sometimes covering parts of the teeth. In severe cases, the teeth may loosen and fall out. Frequently, a mild case is mistaken for either an acute stomatitis or an inflammation due to difficult dentition.

When such symptoms fail to respond promptly to local treatment, suspicion should be aroused, and search should be made for tenderness in the long bones, a periosteitis of varying degree being another rather constant symptom. Enlarged abdomen and pasty color are other suspicious symptoms. Proper treatment of the general condition will relieve the mouth symptoms without any local treatment.

Case. A baby ten months of age was seen with a marked inflammation and hypertrophy of the oral mucous membrane. The child had been perfectly well up to six months, but for a number of weeks had shown a gradually increasing soreness of the mouth which had made eating difficult. The little patient had been under treatment by a good dentist, but mouthwashes, cauterizing, and curetting all failed to give relief. This aroused my suspicions. A physical examination revealed extremely tender shin-bones, any pressure whatever causing pain. Careful questioning as to feeding soon established the probable diagnosis. Under the direction of a pediatrician a proper diet was prescribed, which included a liberal allowance of fruit juices. The mouth symptoms promptly disappeared without local treatment.

With adults, again, our fundamental truth holds good, that departure from normal in various organs of the body may be followed by retrograde changes in the mouth.

DISTURBANCES OF THE GASTRO-INTESTINAL TRACT.

II. In disturbances of the gastro-intestinal tract, aphthous stomatitis is occasionally seen which is stubborn in yielding to local treatment but which clears up under treatment of some general condition.

CANKER.

III. Canker is another condition observed in patients with high acidity in

the stomach or in a debilitated condition. We have little or no exact knowledge concerning canker. While it is not serious from a pathological standpoint, it is extremely distressing, especially in the recurrent type, and seems worthy of more attention, particularly as regards its etiology.

CONDITIONS SIMILAR TO PYORRHEA THE RESULT RATHER THAN THE CAUSE OF GASTRO-INTESTINAL DISORDERS.

IV. The fact that chronic low-grade inflammatory conditions of the mouth similar to pyorrhea alveolaris may be secondary symptoms of a disordered gastro-intestinal tract is also worthy of serious consideration. Two cases, briefly stated will illustrate my point.

Case 1. Woman, fifty-five years of age, for twenty years under treatment for pyorrhea by one of our best known dentists. The teeth and gums were maintained in fairly healthy condition only by faithfulness on the part of both patient and dentist. If treatment were discontinued for any reason the teeth began to give trouble. The patient was not in good general health. A year or more ago she consulted a specialist in diseases of the gastro-intestinal tract, who found among other conditions a marked intestinal stasis. As her general condition improved, her dental symptoms improved likewise, and disappeared even with no specific dental treatment for a long period.

Case 2. Woman, thirty-five years of age, under observation for five years. Intermittent attacks of pain in the jaws, followed later by discharge of pus around necks of teeth, especially upper incisors; little or no pus between attacks, and no marked destruction of bone or recession of the gum during the period mentioned. These mouth symptoms appeared about the same time as acute attacks of indigestion to which she was subject. In fact, the patient could usually tell when an intestinal attack was coming because of the preceding pain in the teeth. After the intestinal symptoms appeared, pus around the teeth followed. Under general treatment these attacks have been so reduced in number that the patient now goes for months without trouble.

In this connection, the work of Percy Howe of Boston is significant. He has

produced in laboratory animals by a constipating diet an inflammation of the mucous membrane of the mouth and loosening of the teeth practically identical with pyorrhea. Moreover, on the administration of a cathartic the mouth symptoms improve and soon disappear.

V. Another subject for investigation is suggested in the congested and inflamed gums seen so frequently in alcoholics. It seems quite reasonable to me that this inflammation, which frequently goes on to pus formation, is due primarily to a congestion of the liver and of the portal circulation rather than to local causes.

DIABETES.

VI. Again, diseases associated with the kidney, Bright's disease and diabetes in particular, frequently present their early symptoms in the mouth before the patient is conscious of anything else being wrong. In this fact lies a great opportunity as well as a great responsibility for the dentist, since early detection of a condition of this kind may save the life of the patient. Indeed, one or two writers on the subject of pyorrhea have recognized a diabetic form of the disease, as well as a form due to Bright's disease. A recent case illustrates the importance of such detection.

Case. A young woman of thirty years of age complained of severe pain which caused her wakeful nights. It appeared most frequently in the upper jaw on one side or the other, and sometimes in the lower jaw. Clinical examination of the mouth revealed nothing abnormal, and the X-ray revealed no pathological condition. The blood pressure was taken; it was over 200. Urine examination revealed a well-developed case of Bright's disease.

I have the greatest respect in the world for the local treatment of pyorrhea, and I have seen some wonderful results attained by specialists in this work; nevertheless, I do not feel we are doing our full duty unless we see to it that a complete physical examination is also made.

DISEASES OF THE BLOOD.

VII. Diseases of the blood may produce symptoms in the mouth. In a sec-

ondary anemia stomatitis may occur, while in the pernicious type I have seen cases with vague pain and tenderness that considerably interfered with eating. Splenic leukemia, while a comparatively rare disease, presents in the mouth very marked symptoms not unlike those of scurvy. The mucous membrane is soft and inflamed, bleeds easily, and may show marked hypertrophy. In one case this entirely obscured the teeth. Some of these cases might be mistaken for the soft type of epulis.

PREGNANCY.

VIII. Pregnancy, while not a disease, produces changes in the internal structure which in turn will induce retrograde changes in the mouth unless the latter receives proper attention.

RELATION OF THE DUCTLESS GLANDS TO MOUTH CONDITIONS.

IX. The ductless glands unquestionably play a most important part in their relation to a healthy mouth. One scientist has experimentally prevented the normal development of the teeth by removing the parathyroids.

Another authority on the ductless glands declares that "Deposits of tartar on the teeth in all forms of thyroid degeneration are common symptoms, these deposits being followed by retraction of the gum with loosening of the teeth, which are frequently lost." This is a

physician's brief but accurate description of the sequence of symptoms in Riggs' disease.

X. In the cachexias from tuberculosis, cancer, and other chronic diseases, simple and acute ulcerative stomatitis are frequently seen.

There are also other general diseases which present mouth symptoms: of these, syphilis is of course a notable example. In this paper, however, emphasis has been placed on those special conditions in which the mouth symptoms may be an important factor, and which the dentist may be called upon to treat.

CONCLUSIONS.

Analysis of the facts already presented indicate, it seems to me—

(1) The intimate relation of the tissues of the mouth to the tissues of the rest of the body.

(2) The need of as broad a medical training for the dentist as for other specialists in medicine, the oculist or aurist for example, so that this relation may be better appreciated.

(3) The need of closer co-operation between dentist and physician.

(4) The need of definite research to amplify the meager knowledge we have of the subject, with which this paper is concerned.

[See also *Discussion*, as reported under "Proceedings of Societies," this issue.]

Oral Anesthesia.

By HAROLD S. VAUGHAN, M.D., D.D.S., New York, N. Y.

(Clinic given at the annual meeting of the Dental Society of the State of New York, held at Rochester, May 10 to 12, 1917.)

IN considering briefly the advantages of local anesthesia we must not conclude that it entirely takes the place of general anesthesia, but it does fill a very large gap in oral surgery and exodontia between the cases where ether anesthesia and where nitrous oxid-oxygen anesthesia are indicated.

In the removal of impacted teeth where a moderate amount of bone excision is necessary conductive anesthesia with novocain-suprarenin is the method of choice. The operator can proceed carefully but surely, and as a result a clean, non-mutilated wound is left, in which healing is more rapid and after-pain lessened.

For the surgery of infected foci, granulomata, small cysts, fibrous growths, and root-end resections as done in the office, local anesthesia is essential for careful work.

In exodontia for hypercementosed roots, and roots that have been broken off below the alveolar border, by the careful use of elevators and chisel gouges under local anesthesia these operations can be performed with the minimum amount of surgical trauma.

Local anesthesia is also indicated in the extraction of teeth with divergent and curved roots where great care is necessary to prevent fracture or damage to the surrounding tissue.

Local anesthesia is indicated in general dentistry for cavity preparation in the type of patient whose dread of dental pain makes thorough work almost impossible. Conductive and infiltration anesthesia has made this work easier for both

patient and operator, as well as in pulpitis where pressure anesthesia is contra-indicated. In crown and bridge work, local anesthesia makes possible the proper preparation for crowns and inlay abutments, or makes pulp extirpation easy where it is indicated.

Conductive and infiltration anesthesia also has its advantages and indications in patients with heart and kidney lesions who cannot take a general anesthetic, also where nitrous oxid is contra-indicated, in arterio-sclerosis with high blood pressure.

We divide local anesthesia into conductive anesthesia, or nerve-blocking, in which the object is to infiltrate the anesthetic around a larger nerve at a point central to the operative field, and thus block the nerve of power to carry sensation therefrom; and infiltration anesthesia where the operative field is thoroughly infiltrated with the anesthetic solution, thus affecting directly the terminal nerve filaments.

TECHNIQUE FOR MANDIBULAR ANESTHESIA.

With the index finger of the left hand the anterior border of the ascending ramus is palpated, first locating the sharp external border, then the internal border, which serves as a guide for the insertion of the needle. The needle is inserted at a point about 1 cm. above the line of the last molar, the syringe being directed obliquely on a line with the first bicuspid of the opposite side. The needle is then carried in closely in contact with

the internal surface of the ascending ramus to a depth of about 2 cm., and 2 cc. of a 1 per cent. novocain solution is injected, producing anesthesia to the median line by blocking the inferior dental nerve where it enters the inferior dental foramen.

TUBEROSITY ANESTHESIA.

With the index finger of the left hand palpate the malar process of the superior maxillary bone, and insert the needle opposite the second molar at the gingivolabial fold. The needle is carried upward, backward, and inward to a depth of 2 cm. in contact with the zygomatic surface of the maxilla, about 2 cc. of the solution being necessary for an injection. The nerves supplying the molars and bicuspids are thus blocked off.

Infra-orbital anesthesia is used to block off the incisors and canine. With the index finger of the left hand the cheek is retracted, exposing the canine fossa. With the thumb the inner third of the margin of the orbit is palpated, the needle is inserted in the canine fossa and is directed upward to the region of the infra-orbital foramen, to which it is guided by the thumb, and about 1.5 cc. of the solution injected.

INFILTRATION ANESTHESIA.

In producing infiltration anesthesia around the teeth the needle is inserted about 0.5 cm. beyond the gingival border.

The opening of the needle should face the bone, the solution being deposited under the periosteum. Injection should be made both labially and lingually.

CONTRA-INDICATIONS FOR LOCAL ANESTHESIA.

Local anesthesia is contra-indicated in cases of cellulitis, acute purulent osteitis and periosteitis, and in excited, hysterical, and neurasthenic patients where the thought of consciousness during operation produces psychic shock. Conductive and infiltration anesthesia is not indicated in more than a fair percentage of cavity preparations. It should not take the place entirely of sharp, well-cutting instruments and of judgment and care in the selection of the least sensitive portions of the cavity for retention.

It is understood that the field of injection and instruments should be sterile, and the solution non-irritating. Tissues should not be unduly distended or stripped from the bone. Even under a careful technique the injection of foreign material into the tissues may give rise to considerable after-pain.

A mandibular injection may at times give rise to considerable after-pain and soreness, difficulty in swallowing, trismus, or fixation of the internal pterygoid muscle. For these reasons it should not be employed indiscriminately or carelessly.

616 MADISON AVE.

Practical Sterilization for the Dentist.

By LOUIS MEISBURGER, D.D.S., Buffalo, N. Y.

(Clinic given at the annual meeting of the Dental Society of the State of New York, held at Rochester, May 10-12, 1917.)

BY "sterilization" is meant the destruction or removal of all micro-organisms in or on a body or substance. Disinfection has a somewhat analogous signification, but denotes the destruction or removal of infectious microbes, and this may or may not be accomplished without complete sterilization, according to the nature of the particular case in hand.

Antisepsis means the inhibition of the growth of micro-organisms without necessarily killing or removing them, and is especially applied to the checking of microbic activity in wounds and the effects produced thereby (sepsis).

Food preservation involves similar principles, depending upon the prevention of microbic activity in dead organic matter either by sterilization or by the presence of inhibitive substances similar to antiseptics, but in this instance called preservatives.

According to an article which appeared in a recent issue of the *Bulletin* of the U. S. Health Service the sterilization of dental instruments can be accomplished by immersion in phenol for from fifteen to forty-five minutes, 5 per cent. solution being more efficient than pure phenol. As we cannot stop to examine the instruments every fifteen minutes, the outside limit must be accepted.

The most expeditious and reliable method of sterilizing root-canal instruments is without doubt by heat. According to Hasseltine, author of the article above referred to, immersion for three minutes in boiling water or water at the temperature of 80° C. will kill all but the most resistant spores. Inasmuch as we

are not especially concerned with spore-bearing bacteria, but more particularly with the staphylococcus and streptococcus, three minutes of boiling is all that is needed, and anything beyond that may be considered a margin of safety.

An evaporating dish or a similar vessel over a burner on the bracket table or near by enables the operator to use with safety the same broaches over and over again in the same operation. New broaches are not always sterile, because a broach once sterile does not necessarily remain so.

Instruments may be scrubbed with a stiff brush immersed in tincture of green soap and alcohol to remove débris, then placed as above in boiling water, or water at 80° C. Soap (green soap) has a slight germicidal value, which in conjunction with its solvent action on fats and protein and the mechanical cleansing which accompanies its use, justifies assigning it an important place among the chemical disinfectants.

In cases of specific infection, boiling instruments for fifteen minutes is recommended. Sodium bicarbonate or borax should be added to the water to prevent rusting. Calcium chlorid will prevent to a marked degree tarnishing or rusting of instruments, if placed in the cabinet in a glass container without top. It is highly deliquescent, and readily absorbs moisture from the air, and should be replenished every few days.

Steam at 250° F. will kill all spore-bearing germs. The standard method adopted in hospitals for the most refined surgical work is to boil instruments, entirely immersed in the water, for a

period of fifteen minutes or longer, the instruments being thoroughly washed previous to sterilization.

We have here [indicating one of the sterilizers used in the clinic] a sterilizer with which we may sterilize all our instruments, including rubber dam, paper points, gauze, etc., with fifteen pounds steam, corresponding to 250° F., maintained for twenty minutes or longer. This is what hospitals are doing. There is practically no moisture, and the instruments are dry enough when taken out for immediate use.

As to proof of sterility: Dr. A. W. Diack of Detroit, a chemist, uses a tiny closed capsule in which he places a pellet of some chemical composition, which when subjected to fifteen pounds of steam pressure for a few minutes will melt.

This pellet is useful in determining whether or not the operator is following instructions. If the pellet has not melted the process has not been carried out in accordance with instructions.

Gutta-percha cones should be immersed in alcohol. The fingers should be dipped in alcohol or Hogue's preparation of campho-phénique when placing cotton on canal-dressing instruments.

The hypodermic syringe should be kept in a solution of alcohol 2 parts, glycerin 1 part, and the needles placed in a container of alcohol and glycerin as above. Forceps, etc., should be dipped in alcohol and held over the flame before using, as well as having been sterilized. When gauze is sterilized do not have it rolled too tightly.

85 N. PEARL ST.

CORRESPONDENCE

"Septic Teeth: Their Etiology and Surgical Treatment."

TO THE EDITOR OF THE DENTAL COSMOS:

Sir,—May I ask for a little space in the *Cosmos* to suggest a point of view slightly at variance with that of the reviewer of Dr. Josef Novitzky's paper, "Septic Teeth: Their Etiology and Surgical Treatment"?

In the December issue it is asserted that "The larger part of Novitzky's paper is occupied by generalities which are neither particularly new nor interesting to the dental profession. However, this condition is perhaps explicable when we learn that this paper was prepared for a medical and not a dental audience."

I believe that the men of the dental profession on the Pacific Coast, at least, have found a good deal that is distinctly new in Dr. Novitzky's paper, and whether they agree with him entirely or not, they have been very much interested. Moreover, the recent publication in several

eastern magazines of articles along the same line would seem to indicate that other sections of the country are finding interest in the suggestions as to the proper removal of septic teeth. Witness the similar article in the December *Cosmos*.

May I inquire if the reference to "a medical and not a dental audience" implies that a dental audience would not be interested in septic teeth? Let us hope not.

In one respect I agree thoroughly with the reviewer, "Dr. Novitzky is distinctly an enthusiast," be it said to the honor of his profession. His years of study, experimentation, and surgical experience certainly indicate an idealism that should be encouraged, particularly in the dental profession.

Yours truly,

ROBT. BURNS, JR.

SAN FRANCISCO, CAL.

PROCEEDINGS OF SOCIETIES

Northeastern Dental Association.

Twenty-third Annual Convention, at Worcester, Mass., September 26, 27, and 28, 1917.

(Continued from page 158.)

WEDNESDAY.—*Afternoon Session.*

(Continued.)

The next paper presented was one by Dr. LEROY M. S. MINER, Boston, Mass., entitled "The Influence of General Health on Oral Tissue."

[This paper is printed in full at page 234 of the present issue of the DENTAL COSMOS.]

DISCUSSION.

The President. It were too bad if nothing should be said on a paper of this sort, which touches so vitally the matter of our everyday work, and touches so vitally also on the thing that we have been seeking to bring about, that is, a proper recognition by medical men of the dental profession. If we are to have proper recognition, it must be because we are able to render to the patients of the medical men a service they are not able to render, and one for which they must look to us. We hope to have such co-operation from the medical men as we may deserve by our fitness, and to render a service that will bring about such co-operation. There are conditions in the mouth that are obscure and for which we are at a loss to find a cause, and must refer to physicians, just as in the experience of physicians there are conditions for which they cannot find a cause and which they refer to us. When we are able to find the cause and remove it, and render service in that way, we shall have

co-operation from the medical profession. There are cases too obscure for either the medical man or the dentist alone to find the cause, and the paper emphasizes the point that in these mouth cases such as have been spoken of, and which do not respond readily to treatment, if we fail to bring a medical man into the case we fail to render to the patient the service that we are expected to render; just as the medical man would fail if, in certain cases where it is beyond his power to find the cause, he failed to bring the dentist into the case. Those are the cases in which co-operation is necessary in order that we may render to the patient the service that both the medical and the dental profession are expected to render, and through which the professions will be brought more closely together.

Dr. W. R. Pond, Rutland, Vt. In reference to what Dr. Miner said about infantile scurvy: One of my children, three years of age, had a very distressing condition of the mouth, and we were unable to account for it. The physician said that if the child were not in a family of plenty, he would think that she had scurvy. Anyway, the mouth condition cleared up under general treatment and a change of diet, and, as I have thought it over since, I believe it was undoubtedly something of the nature of scurvy. It was plainly a case of wrong diet and the mouth conditions were indicative.

Dr. Miner (closing the discussion). There are two or three points I wish to emphasize, but first I would say that I feel it a privilege to have been in the general practice of dentistry. I believe any specialist should be in the general practice of the profession in which he intends later to specialize.

I realize that ninety per cent. and perhaps more of the dental profession do reparative work and mechanical work connected with restoring teeth that have been lost, but I can see no reason why a dentist who does this work should not have a broad medical training which will better enable him to treat pathological conditions in the mouth, just as an oculist, while he may principally do refraction work, which is a mechanical procedure, must know how to treat the diseased eye. It is a source of gratification to the dentist and to his patients to know that his training makes him more keen and more capable of handling the occasional case that is out of the ordinary. Of course, a specialist sees a larger number of cases of this kind, and his viewpoint is likely, therefore, to be warped, making him feel that these cases are more common than they really are, and that the particular work that he is doing is more important than the general practitioner believes. Nevertheless, I feel that cases of the kind referred to in my paper occur, perhaps, more than occasionally, and are often overlooked. Dr. Pond's remarks illustrate this.

Scurvy is a misunderstood disease. It is not a matter of not being able to get the proper food; it is a question of improper feeding. It is not a disease that occurs always in poor families, but is liable to occur in any family, no matter how well-circumstanced they are, with ability to furnish whatever is necessary in the way of food to their children. These cases almost always occur in families that are able to provide the right kind of food; it is simply because of the fact that they have been misled as to the kind of food that should be given. The milk diet has been continued too long, and the child has not obtained the necessary bone-building materials, which are

supposed to have an influence in keeping away scurvy. Fruit juices are almost a specific in the treatment of the disease.

Dr. Pond. May I interrupt for a minute? The child I spoke of afterward developed appendicitis, was operated on and nearly died, as it was a pus case. She had been ailing for months, and had shown various symptoms, but nothing that would indicate appendicitis.

Dr. Miner. That is extremely interesting, because it adds another point to the truth I am trying to illustrate.

Dr. Manson's suggestion interested me, also. If the medical profession is going to recognize dentistry as a branch of medicine, we must show ourselves worthy. We must show that we do read and are interested in something besides the mechanical restorative work, as Dr. Ruyl has shown so clearly this afternoon. I enjoyed his paper thoroughly. Dentistry is a pretty broad field of work, and properly, to my mind, is a specialty of medicine. If we are to get co-operation between the medical and dental professions, we must show that we are qualified to meet the physician on his own ground. We must show that we appreciate some of his problems and the conditions that he has to consider. It is this that we are looking for, of course; and attainment depends on various things. It depends on the attitude of the profession and that of the faculties of our dental schools, who should recognize this fact and increase the requirements for our dental students. Until that time comes, we cannot hope to stand on a plane with the other specialists of medicine.

Adjourned until the evening session.

WEDNESDAY—Evening Session.

The meeting was called to order by the President at 8.25 P.M.

The Secretary read a telegram of greeting from the president of the National Dental Association. The President stated that he had also received a letter from the same source, but had failed to bring it with him to the meeting.

Dr. R. OTTOLENGUI of New York City gave an extemporaneous lecture on the subject of "The Physical Effects of Ionization upon Diseased Apical Tissues," which was discussed by Drs. Leroy M. S. Miner, Boston, and A. J. Asch, New York.

Adjourned until Thursday afternoon.

THURSDAY—Afternoon Session.

The meeting was called to order by the President at 3 P.M.

WELCOME FROM THE MAYOR.

The President then introduced Hon. P. G. Holmes, mayor of Worcester, who welcomed the society to Worcester as follows:

Hon. P. G. HOLMES. *Mr. President, members and friends of the Northeastern Dental Association.*—I fully realize that you have a very full program outlined for this afternoon, and know you will all be very glad if I make my little say brief. I can assure you, however, that I am glad to come here just to say a few words to you on this occasion, as I want to extend to you the warm greeting and warm welcome of the city of Worcester. We enjoy your meeting, and can assure you that we shall look forward with pleasure to your coming again, and having convention after convention here. If our local organization is not taking care of you properly, we will find out the reason and remedy it. I believe you are in the hands of men who understand their position, men who will take care of all your little wants while you are here, and if they do not, I believe that it is your duty to report that matter to me or some member of the committee, because we want you to feel at home, and we want you to come again. We take a great deal of pride in Worcester, and we want you to take a little of that pride with you when you leave after your convention is over. I can assure you that whenever you come here, either as a convention or as individuals, Worcester will always welcome you and be ready to take care of you in the right way.

A motion picture showing "Extraction of Teeth under Nitrous Oxid Anesthesia" by Dr. J. D. THOMAS was then exhibited.

Dr. Manson introduced Dr. W. D. TRACY of New York, who made an appeal to the members of the association in behalf of the Preparedness League of American Dentists, asking their aid in improving the dental condition of the men in the army.

Lieutenant HECKARD of New York was introduced, and spoke on the Preparedness League's work in the army.

A motion picture, showing the "Extraction of shrapnel from the face and jaw, implanted there as the result of war injuries," was exhibited by the S. S. White Dental Mfg. Co.

The Secretary read a telegram from the sister-in-law of Dr. Saunders, the former treasurer, stating that she had just heard of his safe arrival in France.

The meeting then adjourned until the evening session.

THURSDAY—Evening Session.

The meeting was called to order by the president at 8.15 P.M.

A motion picture showing his method of oral prophylactic Treatment of Pyorrhea was exhibited by Dr. Paul H. Stillman of New York.

A paper was presented by Dr. K. H. THOMAS, Boston, Mass., entitled "Selection of Anesthesia for Oral Surgical Operations, and the Roentgen Ray as an Aid in Diagnosis."

[This paper is printed in full at page 209 of the present issue of the COSMOS.]

DISCUSSION.

Dr. Leroy M. S. Miner, Boston, Mass. I wish to refer briefly to one point, and that is, the use of local anesthesia in connection with general anesthesia. Dr. Crile of Cleveland, a man of great ability as a surgeon, and greater as a research worker, brought this matter to our attention. It has long been known

that although a patient may be unconscious during an operation, he may, even after a very slight one, experience a tremendous shock, this being known as "surgical shock." Dr. Crile undertook to find out what surgical shock is, and, briefly, he found it to be this:

Although the patient may be unconscious and suffer no actual pain, the traumatism is registered as an injury in the nerve cells, and the result is as serious as though pain had actually been felt. To avoid this, we use a method of nerve-blocking by means of local anesthesia to prevent these sensations from being conducted to the brain. That is a point that many surgeons have seriously taken into consideration, and consequently they are habitually using local anesthesia in connection with general anesthesia.

Dr. Wm. H. Weston, Nashua, N. H. I want to ask a question. Before the injection of the anesthetic, Dr. Thoma has told us, he sterilizes the gum with iodine, which is the method employed generally, I believe. Just recently, in talking with a surgeon in central Massachusetts, a man well instructed in all lines of surgery, I mentioned sterilizing the gum with iodine previous to using novocain, and he brought out the point that it is recognized by the medical profession today that the application of iodine to a moist surface has very little sterilizing action; they like to have the parts to which the iodine is to be applied shaved from twelve to twenty-four hours previous to the operation. In the case of the injuries received in many large factories, those in charge are instructed to apply the iodine with the parts dry, and before washing. Now, could we use anything better than iodine? Would clear alcohol be better?

Dr. Thoma (closing the discussion). Just a word with regard to the use of iodine and alcohol. Iodine is an alcoholic solution. The effect you would get from the alcohol you get from the alcohol that is in the iodine. I dry the surface of the gum as well as possible before applying the drug, in that way getting some action of the iodine. At least, that is clinically

evident from the fact that I get no infection when doing these operations in the mouth.

The hour is very late, and in order to give the next essayist an opportunity to present his essay I shall close the discussion. I wish to thank the gentlemen of the Northeastern Dental Association for the interest they have taken in my paper.

REPORT OF THE NOMINATING COMMITTEE.

The report of the Nominating Committee was presented by its chairman, **Dr. BARRETT**, as follows:

Mr. President and members of the society,—The Committee on Nominations begs leave to submit the following recommendations:

President—**Dr. Ira B. Stilson**, Providence, R. I.

First Vice-president—**Dr. William R. Pond**, Rutland, Vt.

Second Vice-president—**Dr. Blake A. Sears**, Hartford, Conn.

Secretary—**Dr. Alvin A. Hunt**, Hartford.

Assistant Secretary—**Dr. Leslie A. Spelman**, Hartford.

Treasurer—**Dr. Roy A. Bush**, Worcester, Mass.

Librarian—**Dr. William A. Young**, Concord, N. H.

THOMAS J. BARRETT, *Chairman*.

WILLIAM R. POND,

ALBERT E. CARY,

JOSEPH E. FARNUM,

C. FRANK BLIVEN, *Committee*.

Dr. BARRETT. I beg leave to amend the report, if there is no objection, by adding the name of **Dr. Irving E. Pendleton** of Lewistown, Me., for editor. The committee overlooked that office. This is a unanimous report of the committee; and as the hour is late, I would move that the secretary be instructed to cast the ballot of the society for the gentlemen nominated by the committee, except the person nominated for secretary, and that the president cast the ballot for that officer. (Motion carried.)

The ballots were cast for the list of nominations as read by the president.

The President announced as the next item on the program a paper by **Dr.**

NORMAN B. NESBETT, Boston, Mass., entitled "A Simple Form of Removable Bridge Work with Cast Clasps."

[This paper is printed in full at page 204 of the present issue of the COSMOS.]

DISCUSSION.

Dr. I. B. Stilson, Providence, R. I.

Probably the most serious objection to this class of work is the subsequent decay of the enamel under the clasp. I believe, however, that this can be entirely overcome. I see no reason why a tooth should decay more readily where it is in contact with a clasp than when it touches a neighboring tooth. It is a matter that rests entirely with the patients as to whether they are going to keep their teeth in a sound, healthy condition or allow them to decay. There is something interesting to me in the case shown in the slide, in which two molars had been lost and the bridge placed from the second bicuspid to the third molar. I can testify to the comfort and durability of a clasp of that kind, as I am wearing one of Dr. Nesbett's bridges, and it is giving entire satisfaction.

Dr. Nesbett (closing the discussion). I have not very much to say, except to agree with Dr. Stilson. If we admit that we are going to have decayed teeth, we are going to have them; that used to be the attitude of the dental profession toward the public. It is a question of prophylaxis; if we are not careful of the enamel surface, we will get decay. I have seen it, and they say that this type of clasp causes it; but I do not expect to have decay, nor does Dr. Stilson, ten years hence. There are disadvantages in every kind of work devised; you cannot get perfection in any one way. I think the feature of decay is a minor consideration.

A moving-picture film showing the operation of Bone-grafting, as performed by Dr. Fred H. Albee of New York City, was exhibited.

The meeting then adjourned until the Friday morning session.

FRIDAY—Morning Session.

The meeting was called to order by the president at 10 A.M.

The Secretary read the report of the Committee on the President's Address.

On motion of Dr. STILSON, the report was accepted.

On motion of Dr. EDWARD S. ROSENBLUTH of Bridgeport, Conn., the president was directed to appoint a committee of five to formulate plans for the carrying out of the recommendations of the committee that had just reported. Dr. Manson stated that he would appoint that committee at the close of the meeting.

On motion of Dr. STILSON, the society decided to remit the dues of all its members who are serving in the United States army during the time that they remain in service.

The President then introduced Dr. HERBERT L. WHEELER of New York City, lieutenant in the Dental Reserve corps, who read a paper entitled "The Relation of the Surgeon and the Dentist in Face and Jaw Injuries."

[This paper is printed in full at page 220 of the present issue of the COSMOS.]

DISCUSSION.

Dr. Thomas J. Barrett, Worcester, Mass. What Dr. Wheeler says with reference to the lack of knowledge on the part of the average dentist who has applied for admission to the Dental Reserve corps is absolutely true, and recent examinations have clinched the facts as he states them. His paper is an arraignment of the dental profession for their lack of knowledge along certain lines. I do not believe that this is the result entirely of college training and poor teaching. I think that is true to some extent, but it is due to other causes as well.

As I understand Dr. Wheeler, he desires to call the attention of the profession to our lack of preparedness with reference to meeting and treating the

conditions with which we are soon to be confronted. How much this lack of preparedness to meet the present crisis may be chargeable directly to the dentist, and how much to our national deficiencies in not preparing men for this line of work, I am not ready to say.

How many men practicing in this city have had opportunity to treat fracture cases? How many, when they did have such an opportunity, have availed themselves of it, and how many have sought for an opportunity? The larger number would be those who have avoided them. How many of the schools have taught and insisted upon the treatment of fracture cases by dental students? How many have sent their students to hospitals and infirmaries where they would have a chance to meet and treat these cases? You see, the responsibility is not all on one side, it is divided. How many practitioners of dentistry have ever seen a gunshot wound?

I have been connected with one of the hospitals in Worcester for many years, have treated fracture cases, and have always had more or less difficulty in getting men willing to assist, and to devote their time and energy to treating these cases. There is no money reward in treating fracture cases. Of the many I have attended, I have been paid for very few; of the few, it has been some corporation by whom the man was employed that paid my fee—rarely ever the patient. It is not an inviting field for dentists to work in from a remunerative point of view.

What Dr. Wheeler is trying to convey is that there is now urgent need for men to come forward who have had special training in oral surgery and fracture cases. The Government is amply supplied with dentists to do repair work on the teeth of soldiers. Twenty-eight hundred have been commissioned, and that is the number allowed by law for the 2,800,000 men who are to be enlisted; but there is urgent need for men who have had some surgical experience, and who can do the work that Dr. Wheeler says will soon be forced upon us, and which will demand our skilful attention.

I understand that the Surgeon-general is now creating what are to be known as *head units*, where men of experience in oral surgery will work with the general and plastic surgeons as well as with the nose-and-throat men and the eye-and-ear men. These various specialists will work in harmony to put the injured men back into society in a healthy as well as a slightly condition. I do not know how we are to meet that demand now, but I do think that the profession will fully meet it. When called upon, I believe we shall have a sufficient number of men of ability to come forward and meet the responsibilities, and show that in the dental profession we have men who will measure up with any other medical specialists. This can and will be done by the dentists of this country as well as by those of any other country now engaged in this terrible conflict. Our men are as well equipped and better trained than any dentists in the world.

It is a terrible reflection on the dental profession, but I know it to be true, that we have some men who are now seeking commissions who are without ability to diagnose the simplest oral condition, and who do not know the blood and nerve supply of the teeth. Dr. Wheeler's examinations have revealed this fact, and other examiners doubtless will confirm his findings. It behooves us to prepare for this demand, and to prepare quickly. The young men going into the work should spend every leisure moment in preparing themselves for the call that will be made upon them. I think we owe Dr. Wheeler a debt of gratitude, for it is not every man who would take the bull by the horns and present the conditions as he has found them. It is not a pleasant thing to do, but he has pointed out our weak spots, and told us how we can overcome them, and how we can prepare ourselves to meet the conditions that will confront us.

I have been asked to take up another phase of the subject. There are a number of men in the profession, who, loyally responding to the call of duty, have received commissions as lieutenants in the dental corps, have closed their offices,

have turned over their practices to others, and have done everything they could to prepare for duty. It seems that the Government has at present all the operating dentists needed, and many of the men commissioned have no assignments. These men are much disturbed over present conditions as well as the future. There is no demand for them now, and only those who can specialize will be called or accepted. If Dr. Wheeler could tell these young men what their status is and what their future is likely to be, it would be of value not only to those here, but to many others in similar positions.

Dr. M. E. Pierce, Cambridge, Mass. What proportion of those who present themselves for examination as dentists succeed in passing the examination?

Dr. Wheeler (closing the discussion). I shall close the discussion on the paper first, and then answer the questions of Dr. Barrett and Dr. Pierce.

I am glad Dr. Barrett brought up the question he did, because there is much confusion in the minds of the profession and the public, and especially of the exemption boards, with regard to this subject. My paper was not written as an arraignment of the profession. As a teacher, it is my custom to get down and have heart-to-heart talks with my classes when I think they are not doing well, to point out to them where they are lacking, and endeavor to get them to overcome the deficiency. My thought was that we are confronted with the greatest conflict that the world has ever seen. I think very few men in this country appreciate the gigantic nature of this war. I scarcely appreciate it myself, although I have been twice in Europe and twice in England since war was declared. I have seen the troops of Belgium, France, England, and America marching into this war. I have seen the wounded from the western front in large numbers, in France and in England; I have seen the German prisoners in their pens, and in the Val de Grâce Hospital the wounded Germans, and the scale on which this conflict is being waged is something almost beyond human comprehension. I think I could

almost say, without being brutal, that the man who is killed is often more fortunate than the man who survives.

Now there will be in this country, as there are already in France, in England, in Belgium, and in Italy, a very large number of men with severe wounds about the head and face. Trench warfare, as you know, lends itself particularly to that type of wound, and while I do not think the proportion is so great now as in the beginning, or so great as has been claimed, it is still sufficiently great to be appalling. When these men begin to come back here, the dental profession must be in a position to work harmoniously with all possible forces to alleviate these conditions, and the object of my paper was to persuade all men who feel that they are in the least bit capable of such work, who have an interest in it, and who would like to be of assistance in caring for these mutilated men, to prepare themselves.

It is not strange—Dr. Barrett has given you the reason why it is not strange—that so few dentists do this work. His statement as to the number of fractures in persons able to pay for treatment coincides exactly with my own experience. As the director of the service at Bellevue and allied hospitals, I have occasion to see two hundred or more jaw cases annually; and in the seventeen years that I have been in New York I have never had but three cases that could pay anything—and one of these jumped his bill and disappeared; the others were automobile accidents occurring in people who had means. Nevertheless, it is essential that the dental profession learn to do this work.

Now, to digress a moment, those of you who know of my activities in regard to getting men interested in working for the departments of Health and Schools know that I have never advocated dentists' giving their time or doing work for the Health department or the school boards in New York without compensation. I believe that a professional man who works for the public is worthy of his hire, and the only excuse for dentists' doing this work for the public gratis is

for educational purposes. When that is done, the public should do just what they did in the case of the medical profession. They should appoint dentists to the proper offices, and pay them, as they do physicians. That was done in the New York Health department when I was in position to exert some influence on the question. Physicians and surgeons, however, do give a great deal of their time gratis in hospitals, and there they see these charitable cases. Dentists could do the same thing, giving their services to the hospitals for a certain amount of time. The dentist cannot give so much time as the physician, because his work is of a different nature. We not only diagnose and prescribe in the case, but we also perform the operation and fill the prescription. Furthermore, we are working on organs that, up to a short time ago, have not been considered of very great importance—and for that matter, are not yet considered of much value.

What I urge, then, upon the members of the profession is, so far as possible, to associate themselves with hospitals and with men who have had experience in this line, and get experience. Go back to your books, and study the anatomy of the parts. Go back to your histology and your pathology, and understand, as far as you may, the necessities of the case, and put yourselves in such a position that when you are called upon, as you will be if this war is not over soon and Germany is not whipped, you can meet the demand. We hope that this will be the end of it. Germany claims that she can, in case of necessity, continue the war for many years, but her prognosis has usually been wrong. It is almost a certainty at present that if the Allies keep up their work and hold on, Germany will not only be defeated, but will be crushed—and she *must* be crushed. But before that is done we are going to know what war means in this country, and we are going to know what it means to have acquaintances return with these conditions of mutilation.

My paper was written in an attempt to appeal to the members of the profession

which I have, to the best of my ability, in my weak way and with many mistakes, served for a good many years, and I think those who know me know that when I say a thing to the members of the profession that appears to be harsh, it is because I feel they need it. I say it in all friendship, not as destructive criticism. Therefore I hope you will take this paper in the way I have intended it, and will not only prepare yourselves for the work that I know is coming, but urge your acquaintances to do the same thing. If you do, you will not only be of great value to your fellow citizens and to your country, but you will be doing a great deal for dentistry.

Regarding men commissioned in the Dental Reserve corps, I should like to give a word of advice to those who have rushed into uniform after receiving a commission, and before being assigned to active duty. There have been, up to the present time, fully 2800 dental men who have accepted commissions, and fully 3700 to whom commissions have been tendered, and who can obtain them by taking the oath and accepting the commission. There are only 1200 dentists needed at present at the various cantonments. There are not enough equipments for 500, but this is being rapidly remedied. The Government is doing all it can. If you are commissioned and not assigned to active duty, stay right at your work. Do not run around and assume that you are in the service of the United States Government, for you will not draw one cent of pay until you receive three of those printed notices from the Adjutant-general's office, with the seal of the Government on them—one of which you retain, and two of which you send to the chief quartermaster. When that is accompanied by an attested statement as to the time when you entered the service, you begin to draw pay, and not before. Many men who have received commissions will not be called, because the army is not large enough at the present time to require them, and it will not be, unless an entirely new draft is called for. With comparatively few exceptions, the younger men, recently graduated, are

not likely to be called. Therefore the young men who have been out of school only one or two years and who have positions, or who have practices, should continue their work as though they had not received commissions.

Dr. Louis L. Beach, Bristol, Conn. Will Dr. Wheeler tell us the dental requirements for the drafted men?

Dr. Wheeler. They are relatively simple. The only thing required is that the man have two double teeth above, and two below, which occlude. These may be bicuspid or molars. The number required in the navy is higher; there must be twenty teeth. It should be recommended to the Government that dentists be consulted in each recruiting cen-

ter, as to whether or not the mouth is in a healthy condition. It has been found that the condition of the man is a question of nutrition, his capacity to take care of the food received. In some cases, men with no teeth have done finely and those with many teeth have had to be sent back home because they could not stand the strain. It is a question of vital resistance. The dentist should understand these things, and should be where he can be consulted. Until that is done, the Government will lose the services of a good many men that it should have, and will enlist a good many men who will be burdens to the army, and will have to be sent back home.

(To be continued.)

Academy of Stomatology of Philadelphia.

Regular Monthly Meeting, held November 27, 1917.

THE regular monthly meeting of the Academy of Stomatology was called to order by the vice-president, Dr. Jaquette, at 8 P.M., on Tuesday, November 27, 1917.

The Secretary read the minutes of the preceding meeting, which were approved.

Nominations of officers for the ensuing year were made.

Dr. ROOT spoke of the need of the Preparedness League for subscriptions to carry on its work. This matter was referred to the Council.

Mr. BAILEY, a representative of the Dental Protective Alliance, made a short address.

The Academy passed a motion indorsing the work of the Alliance.

The appointed essayist of the evening, Dr. A. B. Hirsh, was prevented from appearing by a death in his family. In

his place Dr. J. H. DREXLER, Philadelphia, presented a paper on a "Method of Taking Modeling Compound Impressions with the Mouth Closed and Under Normal Biting Strain."

[This paper is printed in full at page 225 of the present issue of the Cosmos.]

DISCUSSION.

Dr. T. D. Casto. I heard our friend Dr. Greene describe his method of taking impressions at the Jamestown Exposition, in 1907; also at the Jamestown Exposition I learned to make gold inlays. My mind was absolutely filled up with the subject of gold inlays, and after coming home I forgot about Dr. Greene's method and did not use it.

I have been very successful in taking upper impressions, but I have to go on record as saying that I do not know how to take lower impressions with modeling compound. Many of my results have

not been as good as I should have obtained from modeling compound, so I think that I shall take some of Dr. Drexler's time, and learn to take lower impressions. I believe I can take an upper impression as well as it can be done, but it takes from half an hour to an hour.

Dr. Drexler. I never take less than an hour.

Dr. Casto. I think I get a good one very often in half an hour. It may not be correct, but it is so much better than what I can do with plaster that I am pleased with it. I usually take from forty-five minutes to an hour in doing this work.

Dr. W. J. Robinson. Modeling compound, to me, is not new by any means, because when I entered dental practice twenty years ago, it was in England. Modeling compound was used in England then, and plaster was comparatively unknown. In all these years I have been using modeling compound in the majority of cases, and have always had success with it, and for that reason have not been inclined to go entirely over to plaster. I have on numerous occasions seen Dr. Drexler do this work, and I have watched his results; they have been very successful. Anything that he says on this subject cannot but be of benefit to us.

Dr. S. P. Cameron. I think that we owe Dr. Drexler a cordial vote of thanks for coming here and taking the time so unfortunately broken up. I did not think one could take a decent impression with modeling compound until I saw it demonstrated. While we have obtained a pretty good idea from what Dr. Drexler has said, I think, on account of the short time he had in which to prepare his paper, the Academy should extend to him an invitation to come before us some other time with a patient and show us his work. He certainly understands taking impressions, does it thoroughly, and does it well.

Dr. W. S. Hewitt. I do not think that the importance of taking impressions can be overestimated. We are losing a lot of teeth, and are finding that bridges we put on years ago have to be

abandoned for some form of removable denture. For that reason, I think the subject of dental impressions is a very pertinent one at the present time.

Dr. H. B. Matteossian. Clinical experience is the ultimate deciding factor in matters of practice, and I recognize from Dr. Drexler's paper that remarkable results can be obtained by the use of his method. There is, however, one question about partial impressions on which I should like to take issue with the essayist.

In the first place, regarding the accuracy of the work. There is no doubt that when plaster and modeling composition are both used with the best technique indicated for each of these substances, plaster will give the sharper impression and more accurate detail. I think this is generally admitted. Now, in the case of an undercut space, where we take the impression in plaster, it is not necessary to build the denture to the full breadth of the space into the undercut. It has been my custom to wax it up with judgment, so that the trial plate will go in place without binding, making it possible for the finished piece to slip in and out with a minimum of trimming. Given these conditions, the plaster impression, taken in the usual way, is preferable, provided the wax is suitably carved before investing. This will give a much sharper impression of all the parts and a better fit than can be obtained with modeling compound. We have all seen remarkable results secured by the use of compound for full dentures, but when it comes to the partial plate, the use of plaster will give better results than if we attempt to do the work with modeling composition. By a person of dexterity, like Dr. Drexler, success will no doubt be obtained with composition in all instances, but for the general practitioner, besides the comparative saving of time, plaster will prove superior, if used in the sensible way of not waxing up to the full width of the undercut space.

Dr. S. B. Luckie. I always admire a man who has faith in his technique. If he has confidence in that, he will make a success of it.

Like Dr. Casto, I saw Dr. Greene, at the Jamestown Exposition, take an impression with modeling compound, but did not pay much attention to it. Those who use modeling compound claim they get an equal impression of the soft and the hard tissues, which they say cannot be done with plaster. Possibly, if someone could work out a technique with plaster, he could obtain the same results with it as those who use modeling compound. I have not yet perfected such a technique. When I have a plate to make now, I endeavor to take the impression with modeling compound, and get a pretty good impression of the roof of the mouth. Then I try to get a good impression under the cheeks and lips, but in doing this it is necessary for me to spend something like an hour and a half or two hours. However, with the little experience I have had with modeling compound, I feel that I can get better results with it than with plaster. But as I do not make more than three or four plates a year, my experience does not amount to much.

Dr. Robinson. I use modeling compound exclusively in crown and bridge work where accuracy is absolutely necessary. A great many dentists make the mistake of not getting the compound cool enough before removing it, and that is why it draws. A number of men take a lower impression with a tray that has a handle on it, and when they take it out, they lift the tray up. The modeling compound is not hard, unless they have used ice-water, with the result that the compound draws and the impression does not fit in the back, when put in again.

Dr. F. A. Fox. I must confess my inability to take partial impressions with modeling compound. I can take the full cases, but the partial cases give me trouble. A great many times, when I have leaning teeth and V-shaped spaces to overcome, I am prone to use plaster in order to overcome the very condition of which Dr. Drexler speaks: this can be done very nicely by paralleling the impression. If you get the impression intact you can parallel the depressions made

by the teeth. In doing so and preparing the cast from the impression we will have the V-shaped spaces eliminated. In this way we get the same result as with modeling compound, and still have the accuracy of the plaster impression. I have obtained the best part of my prosthetic knowledge from Dr. Gritman, who has shown me the most beautiful results. So, in that, I like to follow his method.

Dr. Drexler (closing the discussion). With reference to the question of Dr. Casto, I would say that the taking of a full lower impression with modeling compound is something entirely different from anything that he ever did with plaster. We do not use an impression tray to take a lower impression. The occlusal plane is what I take such an impression with. Supplee says he found out that it could be done with this from one of the dumbest men that he ever tried to teach. After attaching the compound to the bite plate and putting it in the mouth it is cooled and carved down to the arch and the length of the bite. Then we practically have a bite block. We take this occlusal plane, put an excess of modeling compound on the side next to the ridge, and ask the patient to close the lips. The tongue will prevent it from going back too far, and the lips will keep it from going too far forward. The patient is allowed to close down, and we let the compound cool. It does not matter if we have one or two spots where it touches the ridge. We have the start, and we can build up from that. We have the bite and lower impression at one time, and can then build the wings down on each side. The farther down we get the wings along the base of the tongue the less trouble we will have with the lower plate.

A dentist sent a patient to me who was having trouble with a little plate on the lower ridge, in an effort to relieve the trouble the dentist had placed two suction chambers in the plate, one on each side. I took a piece of modeling compound, attached it to each side of the plate, and put it in the patient's mouth to get the wings. Then I told her to

have the dentist put rubber where I had modeling compound. When this was done it was a very successful case.

Dr. Matteossian says that he carves the wax. He is only doing what I do with the modeling compound. I carve the compound.

Dr. Fox says to carve the cast, but how many men are capable of doing it? No man living can get it as it should be. Often you take a plaster impression and lose part of it, and build wax around to take

the place of the lost plaster. Ninety-nine times out of a hundred you do not get it right. Dr. Luckie says that he takes the impressions with modeling compound, and, if they do not fit right, he adds plaster and makes a new impression. That is what Dr. Greene calls the last aid to the injured. I hope some day to give you a demonstration of how you can get an accurate impression of the worst mouth with modeling compound.

The society then adjourned.

THE DENTAL COSMOS

A MONTHLY RECORD OF DENTAL SCIENCE.

Devoted to the Interests of the Profession.

EDWARD C. KIRK, D.D.S., Sc.D., LL.D., *Editor.*

L. PIERCE ANTHONY, D.D.S., *Associate Editor.*

PUBLISHED BY THE S. S. WHITE DENTAL MFG. CO., PHILADELPHIA, PA.

SUBSCRIPTION PRICE, including postage, \$1.00 a year to all parts of the United States, Hawaiian Islands, the Philippines, Guam, Porto Rico, Virgin Islands, Cuba, and Mexico. Canada, \$1.40. To other foreign countries, \$1.75 a year.

Original contributions, society reports, and other correspondence intended for publication should be addressed to the EDITOR, Lock Box 1615, Philadelphia, Pa.

Subscriptions and communications relating to advertisements should be addressed to the BUSINESS MANAGER of the DENTAL COSMOS, Lock Box 1615, Philadelphia, Pa.

PHILADELPHIA, MARCH 1918.

EDITORIAL DEPARTMENT

Dental Scientific Literature.

OVER a quarter of a century ago we published in this magazine a series of articles by the late Prof. W. D. Miller under the general title "The Human Mouth as a Focus of Infection." The papers in question are the embodiment of his findings and conclusions reached after a long period of research dealing with the microbiology of the oral cavity. Among other things Miller's findings made clear beyond all doubt that an infected mouth is a constant menace to the health of the body;—that the mouth is not only an incubator for the growth of a large variety and infinite number of bacterial organisms many of which are pathogens, and that the mouth is the principal portal through which disease-producing organisms find access to the body; but more particularly he furnished incontestable proof by laboratory experiment *in vivo* that

certain mouth organisms were capable of setting up metastatic inflammatory foci in other parts of the body by transmission through the blood tracts—a fact at present well recognized but at that time strongly disputed.

Since the above-mentioned publication of the principles involved in that phase of Miller's researches his findings have been confirmed by the clinical observations of Dr. William Hunter, published in 1911, and further by a large body of subsequent observers, with the result that both in dentistry and in medicine, and to a large degree with the lay public, the doctrines thus set forth have become accepted as the expressions of biologic law.

Moreover, as practical results flowing out of the publication of these discoveries, the whole complexion of dental practice and dental education has undergone fundamental changes that are little short of revolutionary. Formerly a distinct line of demarcation was assumed to exist between what we are wont to designate as operative dentistry and prosthetic dentistry respectively, and it was difficult if not impossible for the purely mechanical dentist to realize that the products of his handicraft involved even remotely any relation to the principles of physiology, pathology, or anatomy. Today these elementary biologic considerations are controlling factors in the adaptation of every dental prosthetic fixture, from a filling in a carious cavity to complete substitutions for the natural dentures. And a still further resultant of these pioneer researches of Miller is the universal recognition of the indispensability of oral hygiene as a means of prophylaxis against local and general disease originating in mouth infection. It is mainly the work of Miller that has in course of time reoriented the dental problem and diverted the attention of the dental profession in a proper degree from the business of repairing dental defects to the larger and more logical problem of preventing them.

No student of dental history can fail to realize the epoch-making character of this pioneer work, yet it has required more than a quarter of a century for the fundamental truths of these researches to bear their legitimate fruit. Miller's early papers were regarded by the mass of the dental profession as the effusions of a scientific dreamer, impractical and without value or helpfulness to the dental practitioner in the solution of his problems. When the *Independent Practitioner* and the *DENTAL COSMOS*

first gave space to these scientific contributions the cry was that they were "uninteresting," "impractical," "too deep," and "over the heads of the majority of dental readers." The demand for the so-called "practical" in dental literature was so general and so insistent that it required no small amount of editorial courage to inaugurate and maintain a policy favorable to the publication of reports of scientific research concerning which the average reader could discern no direct application to his practical needs.

Time has amply demonstrated the wisdom of the editorial policy of keeping the dental profession in touch with the latest advances in scientific research having relation to dentistry. What was at first a scientific dream is today a materialized fact in dentistry as in all other departments of human activity. The principles evolved by Miller a quarter of a century ago are the working formulæ of the present time. His work is still bearing fruit. The recent discovery of the infecting organism of gas gangrene undoubtedly had its origin in Miller's discovery of a group of gas-producing organisms having their habitat in the gastro-intestinal tract and concerned in pulp gangrene and certain types of dento-alveolar abscess. We publish in this issue a continuation of the report by Professor Prinz of his investigations of the diastasic action of salivary enzymes, from which incidentally we quote the following paragraph:

In eating salt-free breadstuffs, unconsciously we reach for the salt-cellar to facilitate the ready munching of the sticky food bolus by rendering it more "palatable." In reality, we activate the salivary amylase to its optimal point, and thereby quickly change the tasteless, pasty mass into a sweet-tasting semi-liquid mixture.

Doubtless to the self-styled practical man the foregoing statement will be regarded as being "over the top" of his comprehension, and will therefore be placed in his category of the impractical. As a scientific truth it will, we think, be classed as a physiologic discovery of the first magnitude. Taken in connection with the findings of Pawlow relative to the nervous response to special stimuli as affecting salivary secretion, the activating function of salt on the salivary enzymes becomes not only an important nutritional factor but an influence controlling the mechanism of deglutition, besides the relation which it bears to caries immunity and susceptibility as shown by Prinz.

No, we have no apology to make for presenting the latest advances of dental science to our readers. There always has been and always will be a certain proportion of readers who complain that it is "over their heads," but when science is really science, then it is the truth—in which case the trouble is with the "heads," and not with the truth, when it overshoots its mark.

BIBLIOGRAPHICAL

SURGERY AND DISEASES OF THE MOUTH AND JAWS. A Practical Treatise on the Surgery and Diseases of the Mouth and Allied Structures. By VILRAY PAPIN BLAIR, A.M., M.D., F.A.C.S., Professor of Oral Surgery in the Washington University Dental School, and Associate in Surgery in the Washington University Medical School. Third Edition, revised so as to incorporate the latest War Data concerning Gunshot Injuries of the Face and Jaws, compiled by the Section of Surgery of the Head, Subsection of Plastic and Oral Surgery, Office of the Surgeon-general of the Army, Washington, D. C. With 460 illustrations. St. Louis: C. V. Mosby Co., 1917.

The third edition of this well-known text-book on Oral Surgery has been revised to meet the demand for a work on this subject that would include the most recent approved methods of treatment of the wounds and injuries received in battle in the present world war, which up to the present have not been embodied in a text-book. The extent and character of wounds of the head and face by reason of modern methods of warfare

have resulted in a closer collaboration between the oral surgeon and the general surgeon, and the author of the present work has made a laudable effort to place in the hands of the student and practitioner the advanced methods being used as the result of the experience of those who have thus far served in caring for the unfortunate victims of the great conflict.

The present revision has been made under the direction of the Section of Surgery of the Head of the Medical department of the army, and while the revision is confined almost entirely to that portion of the book which relates to injuries received in the war, the author has included some very valuable observations on cancer of the mouth.

There will doubtless be, and indeed there have already been presented, many new methods of treating injuries of the face and jaws growing out of the experience of oral surgeons in treating the varied and extensive wounds being received on the battlefield, but the present emergency has created a demand for the collation of all available material for immediate use in preparing the younger men of the profession for war service.

The Medical department of the army is fully cognizant of the need of a comprehensive manual on oral surgery for use in preparing members of the Dental Corps for war service, and has in view the preparation of such a manual, but the immensity of the task and the necessarily incomplete data at present for its preparation has impelled the author of the present work to present the revision of his book in an endeavor to record the data thus far collected in order that it may be made immediately available to dental surgeons who are offering their services to the Government, and we believe that the present work will meet this demand in a satisfactory manner.

The book still retains all the features which have given it a foremost position as a text-book on Oral Surgery.

Books Received.

Books received are acknowledged in this column, and such acknowledgment must be regarded as a sufficient return for the courtesy of the sender. Selections will be made for review in the interests of our readers and as space permits.

REVIEW OF CURRENT DENTAL LITERATURE

[*British Dental Journal*, London, October 1, 1917.]

Further Experiments with the Use of Bone-Grafts, Being Abstracts from Recent German Publications. By W. H. DOLAMORE.

The practical inaccessibility of current German professional literature enhances the value of Dolamore's article. That the operation for the restoration of lost portions of the mandible by means of bone-grafts is still in the experimental stage is admitted by all writers. Nevertheless, such experiments are justified, because a prolonged treatment with a favorable result is better than chronic invalidism.

In the first place there appears to be a con-

sensus of opinion that after the insertion of the graft the mandible must be fixed against the maxilla by ligatures passing between two fixed splints, so as to maintain absolute rest.

Instead of using grafts taken from the tibia, many surgeons now take them from the crest of the ilium. Briefly, the advantages claimed for this selection are—

(1) The operation is shortened, since, the bone being already curved, time is saved in fashioning the graft, hence there is less chance of its getting cold and dry.

(2) The patient is saved the worry of anticipating a weakened leg, which is not wholly visionary.

(3) Union with the mother bone follows more quickly, probably because of the greater amount of medullary tissue, and because vas-

ularization takes place more easily in this spongy bone than in the compact tissue of the tibia.

(4) There is a greater formation of callus, hence the graft grows in thickness and strength.

Imbert, Lheureux, and Rouslacroix (*Revue de Chirurgie*, 1916, p. 111) favor the use of cartilaginous grafts in the repair of facial defects. The graft was disposed of not as a sequestrum, but biologically organized and ultimately replaced by fibrous tissue.

The operators all prefer conductive anesthesia to a general anesthetic. When the operation is performed under a general anesthetic the fixation of the parts must be delayed for twenty-four hours, but no harm apparently results.

During the operation it is possible to expose a portion of the parotid gland. If this portion be small it is preferable to remove it. Failure to do so may result in saliva flowing out of the wound, which may eventually lead to suppuration and the death of the graft.

[*Journal of the American Medical Association*, January 26, 1918.]

The Comparative Efficiency of Local Anesthetics. BY TORALD SOLLMAN.

The clinical desirability of a local anesthetic is determined on the one hand by its anesthetic efficiency, and on the other hand by the degree of local irritation and by the systemic toxicity. The present investigation does not touch on the questions of irritation and toxicity, but is confined to the subject of anesthetic efficiency.

These investigations justify the following conclusions as to the suitability of local anesthetics for clinical uses, mainly from the standpoint of efficiency.

(1) For the anesthesia of the mucous surfaces cocaine, beta-eucain, alypin, and tropacocain are the most useful; quinin-urea hydrochlorid is fairly active; apothecin, novocain, and potassium chlorid are relatively inefficient. Alkalinization increases the efficiency from 2 to 4 times. The solution of the anesthetic salts may therefore be mixed with an equal volume of 0.5 per cent. sodium bicarbonate, without loss of efficiency and with a saving of one-half of the anesthetic. These mixtures, however, do not keep well. The

addition of epinephrin does not increase the efficiency, and is probably useless.

(2) For infiltration and injection anesthesia, cocaine, novocain, tropacocain, and alypin are about equally efficient: beta-eucain and quinin-urea hydrochlorids are intermediate; apothecin and potassium sulfate (or chlorid) are relatively inefficient. The efficiency is not increased by alkalinization. Epinephrin greatly prolongs the action, and should always be added—except to tropacocain. The anesthetic action of potassium sulfate or chlorid is not great enough to be of real value; however, it may well be used in place of sodium chlorid for making anesthetic solutions—1 per cent. solution is isotonic.

In view of the fact that several synthetic anesthetics can completely take the place of cocaine, it would be feasible to prohibit entirely the importation, manufacture, sale, and use of the habit-forming cocaine, except for scientific purposes.

The details of these investigations can be found in full in papers published in the *Journal of Pharmacology and Experimental Therapeutics*.

[*La Odontología Argentina*, Buenos Aires, September 1917.]

A Case of Pyorrhea Alveolaris Treated by Intramuscular Injections of Emetin Hydrochlorid. BY JUAN UBALDO CARREA.

The author believes that he has here to record a case where the happy employment of emetin (intramuscularly) was successful after all other forms of treatment had failed, even the local use of emetin.

The patient was a man of thirty-one, a physician, with a well-marked and extensive pyorrheal infection. Nowhere in this report is there mention made of instrumentation. The context would lead one to believe that at no time was recourse made to the scaling of the teeth and the polishing of the root surfaces.

The injections were carried out by a surgeon. One cc. of the solution contained 0.03 gram of emetin hydrochlorid. The number of cc. injected at each treatment is not told. The injections were made intramuscularly in the gluteal or brachial regions, and repeated every two days until a total of 12 had been made. After the first 4 injections a diminution

of pus was obvious: after 8 injections, still less pus, mastication was less troublesome and painful, the teeth were firmer, and the fetor of the breath had disappeared. Four more injections were given.

The patient suffered no inconvenience whatever. The sole incident upon which he remarked was a slight salty taste. The case cleared up entirely.

Carrea interprets the results as follows: The efficacy of emetin depends upon the time during which it is in contact with the pyorrheal agents to be destroyed. By the intramuscular injection there is a saturation of the system, with subsequent buccal elimination (suggested by the salty taste in the mouth). This insures the desired duration of contact of the remedial agent with the etiological factor in the disease.

Toxic Factors of Some Common Anesthetics. BY EVARTS A. GRAHAM.

The *New York Medical Journal* thus summarizes Dr. Graham's paper: Dr. Graham points out that many of the unexpected and disastrous results which follow operations are due to the effects of narcosis in a more or less direct way. These effects may result promptly or may be several days in coming on. Narcosis is always associated with a state of diminished oxidation and more or less severe tissue asphyxia, and secondarily to these two factors with a more or less marked acidosis. Nitrous oxid has a very slight tendency to induce these toxic effects, ether has a somewhat greater tendency, and chloroform has a very marked tendency to their production. This is due not only to the effects of the narcosis itself in the case of chloroform, but also to the fact that this agent is very unstable, and is readily broken down with the production of hydrochloric acid. The morphological changes in the tissues in late chloroform poisoning are almost wholly due to the effects of the hydrochloric acid. This is shown by the fact that the drug readily yields this acid; that hydrochloric acid induces similar changes in experimental animals; that free chlorin and free hydrogen ions can be recognized in excess in the livers of animals poisoned with

chloroform; that other chlorin substitution products of methane vary in toxicity with the amount of hydrochloric acid which they can liberate; and that the simultaneous administration of suitable amounts of alkali and chloroform results in a marked diminution in the tendency for poisoning to result. Further confirmation is found in the fact that the iodine and bromine substitution products of methane can produce effects indistinguishable from those of chloroform. The halogen substitution products of ethane are similarly capable of causing the same type of lesions. In addition to these toxic effects resulting from the production within the body of a strong mineral acid, or of an asphyxial acidosis, other factors such as acetone may play a part. And, finally, it is to be remembered that the common anesthetics are often capable of dissociating in a way which leaves unsaturated bivalent carbon compounds that may be toxic.

The Porcelain Jacket Crown. BY D. N. LEWIS.

The author constantly emphasizes that this work demands the highest technical skill and the most painstaking attention to every detail. The sinister possibilities of any non-vital tooth, whether intentionally or accidentally devitalized, will make the practitioner welcome those prosthetic procedures which permit the preservation of a tooth's vitality. Lewis firmly believes that the porcelain jacket crown meets this desideratum, and in this sense he calls for its revival and its more general employment. He epitomizes his technique as follows:

Select the shade. This may be advantageously approached by the method of elimination. Prepare the tooth for the reception of the crown. For this the bulk of the enamel is ground away. The cervical circumference is measured to make a band of German silver or copper, 12 mm. wide, which is contoured and festooned. Around the tooth grind a square shoulder 1 mm. in depth just beneath the free margin of the gum. Using the band as a tray, take an impression of the tooth in modeling compound. Take a bite in pink wax, and obtain an impression of the whole region in plaster. The covering of the tooth

with cement brings the first sitting to a close.

Make an amalgam die in the modeling compound impression which was taken in the band. For convenience this die may be set in a plaster base. Using the same measurement wire from which the copper or nickel silver band was made, cut a triangular piece of 1/1000 platinum foil about 2 mm. larger than the length of the wire. This foil is swaged or burnished to the die. The lateral portions of the foil are brought together flatly, so as to fold into a "stovepipe joint" on the lingual surface of the die. The foil is removed from the die, while the die is placed in the plaster impression, of which a plaster cast is run. The bite is applied and the whole placed in an articulator. On separation the platinum foil matrix is replaced on the die, and upon it is built up the desired shade of high-fusing body. This is carved, fused, retouched, and re-fused. The foil is removed, and the jacket crown is ready for cementation in place upon the second visit of the patient.

Technique of Wiring Corresponding Teeth of Superior and Inferior Maxilla in Fracture of Inferior Maxilla. BY EDMUND BUTLER.

Reduce the fracture, judging the results by the occlusion of the teeth. If a tooth is loose in the line of fracture and prevents correction of the position of the fragments, remove it. When the occlusion is correct select the teeth to be wired, usually the first molars on the sound side, the second incisors anterior to the line of fracture, and the first sound tooth posterior to the line of fracture, on the fractured side. If the line of fracture be posterior to the teeth in the region of the angle of the mandible, the inclusion of the first molars on both sides is sufficient. When the fracture is double, only individual judgment will map out a correct procedure.

After the teeth have been chosen as suggested above, separate the jaws. Six cm. length of copper wire, No. 26 or smaller, are cut from a spool such as is used by an electrician. The maxillary teeth are first pre-

pared. Slip the end of the wire through the distal interspace, with a curved hemostatic clamp direct the wire around the lingual surface, and out through the approximal interdental space. Now grasp each end with a clamp and twist the protruding ends, the first twist fixing the wire around the tooth, and continue to twist until about six twists are made, the remaining twists falling into space distally—the wire must be proximal to the surface of approximal contact—and take the shape of the cervical circumference. If these details are fulfilled the wires do not slip, and future adjustments are not needed.

The remaining selected teeth of the maxilla and the corresponding teeth of the mandible are now prepared in the same manner.

Having the wires in place, force the mandible into correct occlusion, twist or hook wires of corresponding teeth together, cut off superfluous ends, turn the rough ends against the teeth and guard each with dental wax or soft vulcanizable rubber.

The patient is nourished by crushed, scraped, or liquid food forced through a catheter passed posterior to the last molar or through the space of an absent tooth.

If unable to use the corresponding teeth, an oblique position of the wires is permissible, so long as the obliquity is in the direction which prevents the deformity from recurring. The wires may be removed from the fourteenth to the twenty-first day. The longer period is usually advisable.

Three Rare Cases of Replantation of the Teeth. BY ANGELO CHIAVARO.

It is of interest to consider Chiavaro's article in connection with the view advanced by John S. Marshall (see DENTAL COSMOS, February 1918, p. 169). Marshall has for a long time advocated the extraction of teeth affected with persistent chronic apical inflammation, their extra-oral treatment and eventually their replantation. In this way Marshall assures us that clinically a large majority of teeth can be saved and made useful members of the dental economy.

Most pertinent confirmation of this attitude is afforded by Chiavaro's paper. Chiavaro has earned the right to be heard with attention,

and his statements must be taken at their face value.

The first case concerns that of a young woman whose four mandibular incisors contained gangrenous pulps. The condition had even progressed to the appearance of a mental fistula. The teeth were extracted, disinfected, the radicular apices were rounded off (to remove the necrosed cementum), and the pulpal cavities were filled with gutta-percha. The fistula was healed, and one week after extraction the teeth were replanted. In about six weeks they became firm, and after almost eleven years they are still firmly in place.

The second case concerns a young lady whose right maxillary second incisor had a chronic abscess. The external plate of the alveolus was destroyed for about one-third of its length, and on the labial surface of the root there was a large cavity communicating with the pulp chamber. The tooth was extracted; a large porcelain inlay was inserted in the cavity, and the tooth replanted. In about one month it had become firm. After the lapse of four and a half years it is still very firm, the gum has not at all receded, but is perfectly normal, even where it is in contact with the porcelain inlay.

The third case is that of a medical student upon whose left mandibular first molar there was a large abscess. It was extracted, and two weeks later it was replanted. Although the socket had been enlarged by Ottolengui's special burs, there was much difficulty in completely reorienting the molar. This was overcome only by the patient strongly occluding his teeth. The replantation was successful.

From these three cases Chiavaro draws the following conclusions: (1) If the alveoli are existing, the contemporary replantation of mono-radiculated teeth is successful; (2) there is a possibility of success in the replantation of a single-rooted tooth, even if a large area of the surface of the root be restored with a large inlay and the corresponding alveolar tissue be absent; (3) if there be great resistance offered to the proper reorientation of a molar (multi-radiculated tooth), success may be obtained, better than by any other means, by the strong occluding of the teeth.

Nowhere in this paper is it made exactly clear why Chiavaro postpones so relatively

long the replantation. Perhaps this delay is to permit time for the eradication of the periapical disease focus. Marshall replants the tooth at the same sitting at which it is extracted.

Perhaps it is significant that the three successful cases recorded here were those of relatively young individuals. The vitality of youth is in general a potent factor in facilitating and accelerating reparative processes. Chiavaro mentions a case where replantation failed. The patient was a woman of forty-six years.

It is regrettable that the author has not offered radiographic data upon the condition of the teeth and their surrounding parts after the lapse of a number of years. This information would be still further enhanced in value if we could have a radiographic record of the condition of the teeth before replantation was resorted to.

Endamæba Buccalis: (II) Its Reactions and Food-taking. BY NADINE NOWLIN.

In the *Cosmos* for September 1917, page 933, is to be found an abstract of Nowlin's first contribution on this organism. In that study we were led to expect in a further report some data upon the intracellular occurrence of *E. gingivalis* in tonsillar tissue. In the present paper no mention is made of this problem. It is to be hoped that this phase of the question has not been abandoned.

The author reveals some unfamiliarity with practical dentistry, and from this standpoint this paper is open to some unfavorable criticism: but obviously the primary purpose of the work was to investigate the biology of the parasite. This forms an interesting contribution.

The material for the present paper was collected from the same source as that of the previous study—a single host and a single point of infection, a maxillary premolar. *E. gingivalis* exhibits a more marked positive thigmotaxis than do free-living amæbæ. It manifests no differential sensitiveness to light. The organisms are very sensitive to thermal changes. "No endamæbæ under observation during this study, though they have been watched carefully for this, have been seen to ingest leucocytes, red blood cells, as

described by other writers, notably Smith and Barrett, or any solid except bacteria and these in small numbers." This is contrary to the conclusions of Goodey and Wellings. (*DENTAL COSMOS*, December 1917. p. 1268.)

E. gingivalis absorbs its food mainly, taking up by osmosis the fluids of leucocytes or other media on which it rests; stores these colloidal substances in vacuoles, and by secretion of its own enzymes assimilates these as needed. The reasons against believing that large food vacuoles are ingested leucocytes may be summarized thus: (1) There is never but one body to a vacuole, while most leucocytes have a one- to three-lobed nucleus; (2) there is never any granular area around the vacuolar inclusions, as would be expected if the cytoplasm of a leucocyte were ingested; (3) leucocytes have been surrounded by amœbæ, but never ingested, according to Nowlin's observations; (4) the whole system of vacuoles can vanish from an *E. gingivalis* exposed to unfavorable conditions sooner than would be possible if these were solid inclusions; moreover, the leucocytes outside the endamœba are left intact.

This method of food-getting by absorption would explain the shrinkage of gums where *E. gingivalis* is present. There appears to be no evidence that these organisms penetrate epithelial cells, but there is abundant evidence that they draw supplies by applying themselves to the surface of the tissues and by crowding between them.

[*La Restauration Maxillo-faciale*, Paris, November 1917.]

The Oculo-cardiac Reflex in Cases of Contractures of the Jaws. BY R. DUCHANGE.

This reflex is manifested by a diminution of the number of radial pulsations under the influence of pressure on the eyeballs. The reflex has been observed among the wounded affected with traumatic ankylosis of the limbs.

For the present purpose two series of individuals were taken, (1) those with fractures without contractures, and (2) those with contractures. In the first series the diminution in the number of pulsations was only by about one-fifth, which is normal. In the second series the mean diminution was by one-half.

The figures indicate that among those with

maxillary contractures, the oculo-cardiac reflex is positive. Consequently these patients come under the general law.

[*Journal of the National Dental Association*, January 1918.]

The Treatment of Root-canals with Putrescent Pulp. BY CARL J. GROVE.

The tooth is radiographed to supply data upon which the treatment may be planned. A sterilized rubber dam is applied, including as few teeth as possible, because every tooth is an additional source of contamination. After it has been applied the rubber dam and the isolated teeth are painted with full strength tincture of iodine, which is shortly washed off with ethyl alcohol. At the first sitting do not attempt to enter the canal to any extent. To do so might force septic material through the apical foramina. Apply chloral hydrate and thymol, equal parts, in a small amount of alcohol, to neutralize the chemical tissue irritants in the canal's putrescent material, and to kill the micro-organisms. This dressing is hermetically sealed in, to be left three or four days, or even for one week with impunity.

At the second sitting, after preliminary isolation and attempted sterilization of the teeth—this of course must be done at each sitting—an effort is made to cleanse the canals with a sterile barbed broach. No attempt should be made to reach the apex. Grove insists strongly that whatever instruments are needed at this or any other visit must be sterile. After the canals have been fairly well cleaned, flood the chamber with alcohol and dry with hot air. There are three reasons for using alcohol at this time—(1) for further sterilization, (2) desiccation before application of medicaments, and (3) desiccation to inhibit bacterial growth. Grove regards this procedure as a very important step in the treatment of septic root-canals. Into the canals is now sealed a dressing, as at the conclusion of the first sitting.

At the patient's third visit a serious effort is made to cleanse thoroughly the canals. The author mentions the use of the sodium-potassium alloy, and of acids, in this connection. The material for the definitive filling, as far as Grove puts himself on record in this paper, is left to the individual practitioner's discretion. The canals should never

be filled if the seepage of serum persists in discharging from the apex.

There are three salient points to this paper, which while not original, are yet perhaps not as generally appreciated as they deserve:

(1) The strictest possible asepsis in all details throughout the whole treatment.

(2) The initial treatment, which essentially consists in the application of an anti-septic and neutralizing agent to the putrescent contents of the canal. These contents are disturbed at first as little as possible. This step is a precaution to prevent the mechanical forcing through of toxic material into the periapical tissues. This second point is really only a phase of the third and following point.

(3) The most scrupulous care not to irritate the periodontal ligament in any way. Any agent or procedure which would tend to weaken the vitality and health of this structure would expose to defeat the whole purpose of the entire treatment. For this reason, Grove dwells on the dangers of forcing part of the putrid canal contents through the foramina, of allowing any sterilizing or cleans-

ing agent employed in the canal to extend to the apex (avoid those irritants, *e.g.* formalin, which are not decidedly self-limiting), or of attempting to enlarge the foramina mechanically. By so doing the periodontal ligament at the orifice will surely be destroyed or injured to such an extent that it may become diseased.

[*New York Medical Journal*, January 12, 1918.]

Relation of Chronic Infection to Thyroid Deficiency. BY HARVEY G. BLACK.

This report appears to be but a summary of a statistical study, which it is to be hoped will be published in full. There were a hundred patients in his series. Oral sepsis and inflammatory diseases of the gall-bladder and appendix played an important rôle in the relation of chronic focal disease and hypothyroidism, comprising 63 per cent. of the 255 infections present in the series. Oral sepsis, including tonsillitis, root-abscesses, pyorrhea, sinusitis, etc., represented 36 per cent. of the total infections, and occurred in 56 of the cases.

PERISCOPE

Relief of Post-extraction Pain.—It often happens that extreme pain follows the extraction of a tooth or root. Almost immediate relief may be given the patient by inserting a pellet of cotton wet with chloroform to the full depth of the root-socket, and placing the finger firmly over the mouth of the socket for from ten to twenty seconds; then remove the cotton from the socket. Repeat if necessary.—H. A. CROSS, *Dental Review*.

Veronal and Novocain to be Made in America as Barbital and Procaïn.—The Federal Trade Commission which has already issued licenses to three manufacturers to make salvarsan in the United States under the name of Arsphenamine, has recently issued a non-exclusive license for the manufacture of veronal to the Abbott Laboratories of Chicago. It is stipulated that the name

Barbital shall appear on the package together with the scientific name diethyl-barbituric acid. The name veronal may also be used on the package in an explanatory sense. The commission has also issued licenses to the Recto Chemical Co. of New York, and to the Farbwerke-Hoechst Co. of New York, for the manufacture of novocain under the German patent, with the stipulation that it shall be designated as Procaïn. The licensees are required to pay 5 per cent. of their gross receipts to the Federal custodian of alien property. The commission reserves the right to fix the prices on these drugs if it should become necessary. These three synthetics are the first for which licenses to manufacture have been issued under foreign patents by the Federal Trade Commission, and physicians would do well to make a note of the new names assigned to the drug by the commission.—*N. Y. Med. Journal*.

Tempering Small Tools.—Fill the tin top of a catsup bottle with melted beeswax, and place conveniently on the work-bench. When tempering hold the instrument—as a chisel—above and near the wax; with the blowpipe heat to a dull red, and quickly push the instrument into the wax. The degree of hardness depends on how rapidly the instrument is pushed into the cold wax.—J. T. SEARCH, *Dental Review*.

An Aid in Crown and Bridge Soldering.—The Richmond crown and certain parts of bridge work present difficulties in the soldering technique, due to the fact that the solder refuses to flow into those V-shaped spaces at the gingival portion over the facing. This may be overcome by clipping up some scrap 22-k. plate, fluxing it, and partly filling the space with this scrap; then continue in the usual manner. These bits of scrap also serve to advantage in preventing the solder from reducing the karat of the cap and backing.—*Pacific Dental Gazette*.

To Hold Cotton Rolls in Place While Operating.—Frequently a cavity may be kept dry long enough for a treatment or for the placing of an amalgam filling by the use of cotton rolls without the rubber dam. The problem is to keep the rolls in place, particularly in the lower jaw, where the tongue always has a tendency to toss them out of position. This may be obviated by slipping an ordinary rubber dam clamp over the tooth after the rolls are in place, allowing the beaks of the clamp to grasp a small portion of the roll between the clamp and the tooth. This will hold the roll securely, and will also prevent the clamp from hurting.—*Dental Review*.

How to Get the Best Results in Casting Watt's Metal Plates with Porcelain Teeth.—After the wax model has been properly invested in a casting flask allow the investing material to dry for one hour. Then place it on a low flame for forty-five minutes, and on a high flame until the whole investment block is red-hot. In order to prevent the checking of teeth which is likely to occur by the difference in the expansion or contraction of Watt's metal and porcelain, the flask should be allowed to cool for thirty minutes. Melt the Watt's metal, pour it in the flask, and allow it to cool. As I have cast Watt's metal for a number of years with the best results, I am positive that some fellow dentist will profit by adopting this method.—JOHN V. AMENTA, *Dental Review*.

Free Dentistry in New Zealand.—The Auckland Hospital and Charitable Aid Board established in 1909 a free dental department for the benefit and accommodation of those who are not able to have their teeth properly taken care of in the community, since which time 23,555 persons have made application for treatment. During the time which has elapsed 18,530 teeth have been extracted, 11,919 fillings put in, and 1264 vulcanite dentures made. The staff at present comprises two dental surgeons and two attendants, besides a number of honorary members of the staff who have given their services free of charge. In return for this free service the hospital board has given the dental association free use of a portion of the hospital for housing a valuable dental museum presented by a prominent individual of the city of Auckland. It seems that at present there is no very marked shortage of dentists in this part of New Zealand at least, but owing to the additional year added to the course of study, making it four years before graduation, there are but few young men willing to give that time to enter the profession.—CONSUL-GENERAL ALFRED A. WINSLOW, Auckland.

Should the X-Ray Diagnosis Supplement or Supersede the Clinical?—In a broad sense, and generally speaking, the X-ray should be used to substantiate, supplement, and amplify the clinical diagnosis. By following this plan one's skill in clinical diagnosis may be very highly developed, while if the reverse order were adopted the clinical art would be lost. The use of the X-ray tends strongly to lead one away from a clinical study of his problems. Exceptionally the clinical picture is so obscure that it becomes necessary to depend almost entirely on the X-ray findings for a diagnosis. This is especially true where there are no local subjective symptoms, and where the objective and remote symptoms are poorly defined. This type of cases is to be found among the chronic apical infections, supernumerary, unerupted, and deeply buried teeth, etc. With these exceptions we still have the majority of cases in which a clinical diagnosis may and should precede the X-ray study. On the other hand, especially in acute pathology, the clinical manifestations may be the only dependence in making a diagnosis. In the early stages of acute inflammation, before any gross destruction of tissue has taken place, the X-ray findings are unsatisfactory. This is likewise true in acute extensions of pathologic conditions surrounding chronic foci.—R. J. WENKER, *Dental Review*.

To Avoid After-Pain in Extraction.—Pain following extraction is usually due to the fact that the socket contains no blood-clot. The condition usually occurs in sockets where the normal outline has been destroyed. It is seldom that the clot will remain in an injured socket. Without the protection of the clot the socket becomes infected, and pain results in a few days, if it has not persisted since the time of operation. Dry socket occurs also as the result of the use of hydrogen dioxid. The action of this preparation breaks up the clot and it becomes infected or falls entirely out of the socket.

The treatment of these cases is to cleanse the socket and apply some agent which will be both antiseptic and anodyne. A good rule to follow is to apply this treatment to all sockets where a difficult extraction has been made. The remedy which I employ consists of a combination of chloretone and essential oils which is put out by Parke, Davis & Co. under the name of Dentalone. This remedy proves very efficacious. The chloretone is both antiseptic and anodyne, and the pain is quickly controlled. The essential oils prevent the dressing from becoming foul in a short time, as is the characteristic of most dressings which are employed. Twenty-four hours is not too long, and even forty-eight hours will bring the patient back the dressing still retaining the odor of the essential oils.—J. P. HENAHAN, *Dental Summary*.

A Method of Filling Root-canals.—Open the pulp chamber until the root-canals are easily accessible, and then proceed to enlarge them to the best possible advantage with a fifty per cent. solution of sulfuric acid. Neutralize this acid and thoroughly dehydrate. Fill the canals with Callahan's resin solution and pump it to the root-apex with a fine, smooth broach; then dry with hot air. This hermetically seals the dentinal tubuli. Eucalypta-percha compound is then used as a canal lubricant. This compound, when cold, should be very heavy and stiff, or in a molding stage and not a flowing stage; it should be heated to a temperature of not less than 200° F. in a water-bath, at which temperature it will be found to be very soft, and to flow very readily. This hot eucalypta-percha compound is then pumped into the canals, using for this purpose a very fine, smooth broach. As soon as the operator is satisfied that the canal is filled to the end with this solution, a small point of gutta-percha is introduced into the canal. The smooth broach is at once forced down along the side of this point and room is made for a second one,

which is sent gently to its place alongside the first one. This is repeated until the small, smooth broach can no longer be forced into the canal to make room for additional points of gutta-percha. The canal then should be filled to within approximately one to three millimeters of its mouth. A point of larger dimensions is then inserted that will just about fill the mouth of the canal. This is pressed firmly to place with large canal pluggers, and lastly given two or three light blows with a mallet to firmly seat the entire mass. This will give you a canal filling that by no means is proof against failures, nor is it above criticism, but the technique is easily mastered and can be put into thoroughly successful practice by any dentist. The time consumed by this method is but little if any more than that of the other techniques, and in my hands has been more successful.—I. L. FURNAS, *Dental Summary*.

Surgical Technique of Root Resection in Granuloma Cases.—A crescent-shaped incision through the gum tissue and periosteum is made approximately three millimeters above the cervical line, or below it for a lower tooth, and the periosteum with its superimposed gum tissue is elevated with a periosteotome to a point one millimeter beyond the apex of the tooth to be operated upon. The incision must be sufficiently large to give an unobstructed view of the operative field.

If the outer plate of bone is intact it is burred, chiseled, or curetted away to the diameter of the pyogenous granuloma, and this pathologic tissue may then frequently be removed from the crypt intact, excepting its immediate circumferential attachment to the periphery of the pericementally denuded root. The exposed apex and the crypt is then sponged with ninety-five per cent. phenol, being careful not to touch the soft tissues with the acid.

A No. 9 round bur is used to resect the root to the point where it is supported by the pericemental fibers which are attached in the canaliculi of the alveolar socket and between the lamellæ of the cementum, beginning the resection at the apex of the root.

The remaining root-end is then rounded peripherally and polished with mounted cylindrical stones. A self-retaining cavity is then prepared in the root-canal, and filled with sterile amalgam. Before the amalgam is inserted the crypt should be freshened with the curet and sterile cotton pellets packed into the crypt, around the mesial, distal, and lingual aspects of the root-end, and the cavity

for the reception of the amalgam filling sponged with phenol, followed with seventy per cent. alcohol.

The filling must be smoothed off flush with the cavity margins, and the pellets of cotton removed, carrying the excess of amalgam from the crypt. The crypt is then flushed free from debris, dried, and sponged with tincture of iodine, followed by seventy per cent. alcohol. The retracted muco-periosteal flap is then released and sutured back to position with interrupted horse-hair sutures, bringing the knots crownward below the suture line, cutting close to the knots.—CARL D. LUCAS, *Dental Summary*.

Orthodontic Nomenclature.—The Committee on Nomenclature of the American Society of Orthodontists recommends the use of the following terms:

Neutroclusion to designate such malocclusions as are characterized by normal mesiodistal or normal antero-posterior relation of the lower arch to the upper arch.

Distocclusion designates such malocclusions as are characterized by a distal or posterior relation of the lower arch to the upper arch.

Mesioclusion to designate such malocclusions as are characterized by a mesial relation or anterior of the lower arch to the upper arch.

Malpositions of the teeth to be defined as the relation which the individual teeth bear to the line of occlusion, the median line of the face, and the individual denture.

Mandibular teeth to be used in preference to lower or inferior teeth.

Maxillary teeth to be used in preference to upper or superior teeth.

Mesioversion—A tooth which occupies a position too near the median line of the face.

Distoversion—A tooth too far from the median line of the face.

Buccoversion—A tooth which occupies a position buccally to the line of occlusion.

Linguoversion—A tooth which occupies a position lingually to the line of occlusion.

Supraversion—A tooth which is too long as related to the plane of occlusion.

Infraversion—A tooth which is too short as related to the plane of occlusion.

Torsiversion—A tooth which is rotated on a perpendicular axis.

Transversion—A tooth which is in the proper vertical plane, but is in incorrect numerical order.

Perversion—An impacted tooth lying in an abnormal plane.

Deformity of the jaws to be used in refer-

ence to extreme malformations and maldevelopments.

Macromandibular deformity—A mandible which is too large.

Micromandibular deformity—A mandible which is too small.

Macromaxillary deformity—A maxillary which is too large.

Micromaxillary deformity—A maxillary which is too small.

Orthodontia to be used for the practice.

Orthodontics to be used for the science.

Orthodontic to be used for the adjective.

Orthodontist—One who practices orthodontia.

These terms were presented to the society in open meeting and adopted.—*Dental Items of Interest*.

KCNS in Tobacco.—We were recently informed that the greater amount of sulfocyanates in the saliva of smokers was due to the presence of salts of HCNS in the tobacco used. As this was contrary to our preconceived notion that the excess of sulfocyanate was due to increased stimulation of the salivary glands, we have spent a little time in studying the subject. Tobacco contains, according to published analyses, various acids, among which are acetic, butyric, propionic, and valeric acids, creasote, and traces of caproic, caprylic, and succinic acids, but no mention is made of sulfocyanic acid. One or two samples of pure tobacco leaf and twelve samples of the manufactured article were tested for the presence of HCNS by extracting the sample with hot water acidulated with hydrochloric acid, then adding ferric chlorid, and shaking out the ferric sulfocyanate with ether. Results were negative in every case, and we are led to conclude that sulfocyanate is not present in tobacco, at least beyond the limits of the test, which Dr. McDonald has shown to be .012 per cent. (See DENTAL COSMOS 1912, page 59.) In making these tests, we have of course decomposed by HCl to a sufficient extent to admit of the formation of ferric sulphocyanate. If HCNS exists in tobacco in some insoluble organic combination not affected by hydrochloric acid or ferric chlorid it is hardly probable it would find its way into the saliva from this source. We have further demonstrated that a degree of heat sufficient to char the organic matter of the tobacco will decompose salts of HCNS. If this is true in a crucible, why not in the bowl of a pipe?—*Proc. Harriet Newell Lowell Society for Dental Research*.

The Hall Method of Making Impressions.—The tray having been made, the steps in taking the impression are as follows: A thin mix of plaster (ordinary impression plaster) is made by taking an excess of water in the plaster bowl, accelerated with sodium chlorid or potassium sulfate, and the plaster sifted in with a small sifter. The plaster passes through the water, and settles to the bottom of the bowl. When, according to your judgment, enough plaster has been sifted in for the impression, decant the excess water, and the plaster in the bottom of the bowl will need the spatula passed through it only two or three times to form a uniform thin mix. This thin plaster is poured into the tray until it is running over, to get the periphery well covered; then the excess is poured out, as it is not necessary to put such an excess of plaster in the mouth, since the tray practically fits the mouth. The tray with the small amount of thin plaster is now placed in the mouth, and with a slight rotary motion slowly and gradually worked to its seat. The tray should be held there with the finger, as it will in many instances become displaced if left for the patient to retain. Many operators use a thicker mix of cast-plaster and do not work the impression up entirely to place, but this procedure deprives us of one advantage which goes a long way toward making the impression a success, viz, compression of the posterior part of the palate. Unless the plaster in this region has the support of the tray to hold it in position, the more or less spasmodic action of the vibrating soft palate will work it down, and prevent pressing contact of the plate, a condition which renders the latter a failure.

When removed from the month after the first attempt with plaster, the impression will show in many places on the periphery that the tissues were drawn taut across the margin of the tray, displacing the plaster and exposing the tray. This indicates that the tray displaced the tissues too much in those regions, and should be trimmed off, so that the same condition will not result after the second attempt.

The palatal portion of the impression may

appear thin and flaky, which indicates that pressure was greater in some places than others, and displaced the plaster accordingly. However, these places do not have to be trimmed or scraped, as that will be taken care of in the next step.

After the excessive peripheral extension is trimmed off we are ready for the next procedure. The first impression is soaked in water so that a second mix will adhere. The second mix, made the same as the first, is poured into the impression, filling it, and pouring off most of the excess, then the tray is carried to place. The mix of plaster should always be made as described in order to get the same smooth, uniform mix, of practically the same consistence, each time.

In trying to remove these impressions it will be found to be a very difficult task. To accomplish this place the forefinger in the palatal region and the thumb above the impression in the canine region on the left side, and press in on the tissue above the impression. This will loosen the impression, and permit it to be removed easily.

When removed from the mouth the second time, the impression should show regular and uniform reproduction of the area to be covered with the denture. The plaster should not be displaced, exposing the compound on the margins; if it does there is still too much displacement of tissues, and the process should be repeated. With a little practice and ordinary care, however, the second attempt with the plaster gives satisfactory results. We are quite sure now that we have the posterior palatal compression, since in each effort we had the soft plaster in small quantity supported by a firm surface.

When an impression is taken in this manner it can be clearly seen that as much peripheral extension may be produced in the denture as we have in the impression, facial contour being the only limit. And I dare say that if proper care is used in not crowding the space where the ramus of the mandible passes the tuberosities, there will be absolutely no trimming necessary on the margins of the denture.—E. B. OWEN, *Dental Summary*.

OBITUARY

Dr. James Beall Morrison.

[SEE FRONTISPIECE.]

DIED, of paralysis at Kansas City, Mo., December 22, 1917, in his eighty-ninth year, Dr. JAMES BEALL MORRISON.

Dr. Morrison, the son of John Rickey Morrison and Sarah Hammond Morrison, was born December 5, 1829, at East Springfield, Ohio, in the public schools of which city he received his early education, which was supplemented by short terms at Jefferson College, in his native state.

About 1848 he began the study of dentistry in the office of Drs. Esterly and Sempler at Stenvenville, Ohio, and continued his studies later with Dr. Hullihen of Wheeling, W. Va. It was doubtless the strongly mechanical bent of his mind that in the first place directed his attention to the practice of dentistry as a profession, and which later, with his highly developed inventive faculty, concentrated attention upon the improvements which he later brought out in various features of dental mechanism, the most prominent and best known of which was the dental engine bearing his name. His mechanical tendencies were doubtless to a degree inherited, his father having been a wagonbuilder and manufacturer of agricultural implements, and an uncle a watchmaker. It was in the shops of both of these that the subject of this sketch in his earlier days found opportunity for the practical training in handicraft which enabled him to personally make many of the tools and instruments which he needed and used in his dental practice. It was the facility thus gained in the working of gold and other materials that gained for him association with Drs. Esterly and Sempler in their dental laboratories, which association a year later took the form of a partnership with Dr. Esterly, and together they traveled among the neighboring towns practicing dentistry, as was the custom in many localities at that early period of dental professional development.

At this same period it was also customary among practitioners of dentistry to submit specimens of their prosthetic work in competition on points of excellence at public exhibitions, and in conformity to that custom Dr. Morrison exhibited before the Ohio State Board of Agriculture in 1852 a specimen denture which was awarded a first prize. Incidentally, as a further illustration of this early custom, it may be noted that it was the exhibition of gold fillings made by the late Dr. Thomas W. Evans at the Franklin Institute Exhibition in Philadelphia in 1847 which attracted the attention of a friend and patient of Dr. C. Starr Brewster, an American dentist then practicing in Paris, through whose instrumentality Dr. Evans was led to go to that city, where he formed a partnership with Dr. Brewster, and thus entered upon his eminently successful career.

In 1857 Dr. Morrison went to St. Louis, where he engaged in practice with his younger brother, Dr. William N. Morrison, until 1861 or 1862, when he went abroad, practicing dentistry in Paris for a year or more with the late Dr. H. J. McKellops of St. Louis, at that time located in Paris, afterward practicing for about six years in London, where he was associated for a time with the late Mr. John Tomes and with Dr. Circombe.

The most notable contributions to dental practice made by Dr. Morrison were his developments of the dental engine and his improved dental operating chair. In August 1870 Dr. Morrison was granted a patent for his bracket engine, a device consisting of a movable arm carrying a handpiece, the combination being actuated either by foot power or other force of energy transmitted to the movable arm through a belt and pulley. The bracket engine was followed by the foot engine, for which a patent was granted to him February 7, 1871. This engine was manufactured and placed upon the market by Johnson Bros. in 1872, the first one being sold at a dental convention held in Binghamton, N. Y., April 17, 1872. Dr. Morrison's inven-

tion of the dental engine thus antedates the invention of Dr. G. V. Black's "Dentist's Helper," a form of dental engine patented by him in August 1871.

Dr. Morrison's improved dental chair was patented in 1887, and was the first chair offered to the dental profession which had provision for a wide range of movement. Previous to the introduction of the Morrison chair by Johnson Bros. the dental operating chair was merely a modification of the barber's chair of that period, and represented by the Perkins, Whitcombe, and Harris types of operating chair.

The Morrison engine was the pioneer of power-driven dental tools, and while in its original form it has been entirely superseded by later and improved designs, to Dr. Morrison belongs the credit of having first demonstrated the practicability of the so-called dental engine. His chair, even though it has been largely superseded by more elaborate mechanisms, is still in use to a considerable extent. If he who causes two blades of grass to grow where but one grew before is entitled to be regarded as a benefactor of his race, surely the impulse given to greater efficiency and more precise technique in dental operations conferred upon the dental profession through the genius of Dr. Morrison clearly entitled him to be regarded as one of the benefactors of our profession, and these data are here recorded that those who are now enjoying the benefits of his inventive talent may not fail to remember to whom the credit is due.

Dr. Morrison was a typical example of that type of practically self-educated, ambitious, and forceful pioneer dental practitioner who so notably contributed to the making of modern dentistry. The type is fast disappearing, a type characterized by a highly developed resourcefulness arising from the urgency of necessity for the creation of means adapted to the ends of dental practice which the present generation of dental practitioners, having at command the elaborate and highly developed armamentarium of modern times, has no occasion to realize.

Dr. Morrison in the later years of his life lived quietly in his home in the midst of his domestic interests. His occasional presence at a dental meeting was his only contact with the dental profession. He was an honorary

member of the Missouri State Dental Society.

On October 23, 1883, he was married at Brunswick, Mo., to Emma Maude Johnson, who with two daughters survives him. His remains were interred at Mt. Washington Cemetery, Kansas City, Mo., December 23, 1917.

Dr. John W. David.

DIED, December 29, 1917, at St. Paul Sanitarium, Dallas, Texas, in his fifty-fourth year, JOHN W. DAVID, D.D.S.

Dr. David, whose death resulted from anasarca together with a nephritis from which he had been a sufferer for several years past, was born at David's Mill, Freestone county, Texas, March 2, 1864. His parents were William and Sarah Carter David, the father being an extensive farmer and miller.

After receiving his elementary education in the schools of Fairfield and Mexia he entered the Baltimore College of Dental Surgery, from which institution he was graduated in 1891, and won the prize for excellence in operative dentistry.

Dr. David joined the Texas State Dental Association at Waco during the same year, and took pride in the fact that he had never missed attendance at an annual meeting of his state dental association. In 1900 he served as president of the Texas State Association. He also held membership in the Southern Dental Association, National Dental Association, Dallas County Dental Society, Navarro County Medical Society, American Medical Association, and was a member of the Committee of Organization in charge of the Fourth International Dental Congress held at St. Louis, Mo., in 1904. During his whole professional career Dr. David was an active participant in the work of the several societies with which he was connected, and was one of the guiding forces not only in his state, but throughout the South, where he exerted a continuous influence in the placing of American dentistry upon a sound professional basis.

Dr. David possessed in a high degree the essential qualities that make for leadership. His magnetic personality owed its charm to his love of the truth and to the unquestioned

moral courage that he displayed upon all occasions as the defender of the principles for which he stood. He was the protagonist of the best ideals in his profession, and the

selfish. The dental profession has lost by the death of Dr. David one of its best exponents, one of its most trusted leaders, and all of his friends a comrade whose friendship has

DR. JOHN W. DAVID.

exponent of a noble and virile American manhood. To his host of friends he was a continual source of inspiration. He was the enemy of no man, but an uncompromising antagonist of all that was mean, petty, or

been a lasting benediction. His remains were interred with Masonic ceremonial at Corsicana, Texas, on December 31, 1917. He is survived by a widow, two sons, and a daughter.

Death of Dr. John R. Callahan.

WE regret to announce the death of Dr. JOHN R. CALLAHAN of Cincinnati, from apoplexy, on Wednesday, February 13th. A full obituary notice of Dr. Callahan will appear in a later issue of the DENTAL COSMOS.

ARMY AND NAVY DENTAL NEWS

Proposed Legislation for the Navy Dental Corps.

THE National Dental Association, at the New York meeting, approved legislation placing the Navy Dental Corps on an equal status with the Naval Medical Corps, similar to the conditions existing between these two corps in the army, as enacted by Congress October 6, 1917. The Legislative Committee was instructed to promote this approved legislation at such a time and under such conditions as would seem most favorable. In this connection, and in view of some of the conflicting and discouraging reports regarding what was secured through the Army Dental Corps legislation, it was deemed advisable to wait for this to be officially interpreted before starting legislation for the Navy Corps. This has just been interpreted to our entire satisfaction, which prompts us to follow the phraseology and general plan of procedure of the Army Corps legislation. Therefore, the following bill was introduced January 5, 1918, by Senator Lodge:

[No. 3386.]

A BILL

TO PROVIDE FOR COMMISSIONED OFFICERS OF THE DENTAL CORPS OF THE NAVY THE SAME RANK, PAY, PROMOTIONS, AND ALLOWANCES AS OFFICERS OF CORRESPONDING GRADES IN THE NAVAL MEDICAL CORPS, AND FOR OTHER PURPOSES.

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled:

That the Dental Corps of the Navy shall consist of commissioned officers of the same grades and proportionally distributed among such grades as are now or may be hereafter provided by law for the Medical Corps, who shall have the rank, pay, promotions, and allowances of officers of corresponding grades in the Medical Corps, including the right to retirement as in the case of other officers,

and there shall be one dental officer for every thousand of the total strength of the Navy and Marine Corps authorized from time to time by law: *Provided*, That dental examining boards shall consist of one officer of the Medical Corps and two officers of the Dental Corps: *Provided further*, That immediately following the approval of this act all members of the Dental Corps now in active service shall be recommissioned in the Dental Corps in the grades herein authorized in the order of their seniority and without loss of pay, rank, allowances, or precedence in the navy: *And provided further*, That nothing in this act shall be construed as in any way affecting the original appointment of officers to the Dental Corps as provided in the "Act approved August twenty-ninth, nineteen hundred and sixteen, making appropriations for the naval service for the fiscal year ending June thirtieth, nineteen hundred and seventeen, and for other purposes": *And provided further*, That when ordered to active duty, officers of the Dental Reserve Corps shall receive promotion in rank under the same relative conditions and provisions of active service as provided in this act for the Navy Dental Corps.

It should be distinctly understood that this legislation is entitled to and should receive the liberal support of the profession generally.

To that end we especially and respectfully request that THE OFFICERS OF ALL DENTAL SOCIETIES PROMPTLY WRITE THEIR SENATORS AND REPRESENTATIVES INDORSING THIS LEGISLATION AND SOLICITING THEIR SUPPORT. It is assumed that all dental societies at some time have indorsed this general legislative program, and it is therefore suggested that official stationery be used in writing, and that you be specific in stating that you express the views of your society. Individual letters are very necessary, especially from those who professionally serve or are acquainted with their senators and representatives; and further, it

is very important that the merits of this legislation be most favorably presented to the members of both the Senate and the House Naval Affairs Committees, as committee support is an essential requisite. (A list of these committees is hereinafter incorporated.) In these letters it can very properly be stated that this proposed legislation is in exact harmony with what was enacted by Congress October 6, 1917, for the Army Dental Corps, and as a question of justice the same condi-

tions should be provided for the two branches of the service.

This appeal demands your prompt attention, and it will be appreciated if you will please forward to me such replies as are distinctly favorable or unfavorable, as this makes it possible to keep in touch with the situation in an advantageous way.

The following is a list of the committees above mentioned as published in the Congressional Directory, April 1917:

SENATE NAVAL AFFAIRS COMMITTEE.

BENJ. R. TILLMAN of South Carolina.
CLAUDE A. SWANSON of Virginia.
JOHN WALTER SMITH of Maryland..
JAS. HAMILTON LEWIS of Illinois.
JAMES D. PHELAN of California.
KEY PITTMAN of Nevada.
THOMAS J. WALSH of Montana.
ROBERT F. BROUSSARD of Louisiana.
PETER G. GERRY of Rhode Island.

PARK TRAMMELL of Florida.
BOIES PENROSE of Pennsylvania.
HENRY CABOT LODGE of Massachusetts.
WILLIAM ALDEN SMITH of Michigan.
CARROLL S. PAGE of Vermont.
MILES POINDEXTER of Washington.
WARREN G. HARDING of Ohio.
FREDERICK HALE of Maine.

HOUSE NAVAL AFFAIRS COMMITTEE.

LEMUEL P. PADGETT of Tennessee.
J. FRED C. TALBOT of Maryland.
ALBERT ESTOPINAL of Louisiana.
DANIEL J. RIORDAN of New York.
WALTER L. HENSLEY of Missouri.
JOHN R. CONNELLY of Kansas.
WILLIAM B. OLIVER of Alabama.
WILLIAM W. VENABLE of Mississippi.
CARL VINSON of Georgia.

ADAM B. LITTLEPAGE of W. Virginia.
JAMES C. WILSON of Texas.
THOMAS S. BUTLER of Pennsylvania.
WILLIAM J. BROWNING of New Jersey.
JOHN R. FARR of Pennsylvania.
FRED A. BRITTEN of Illinois.
PATRICK H. KELLEY of Michigan.
SYDNEY R. MUDD of Maryland.

INTERPRETATION OF ARMY DENTAL CORPS LEGISLATION.

Members of the dental profession will probably be interested in knowing that the legislation enacted October 6, 1917, has finally been satisfactorily interpreted, and that the members of the regular Army Dental Corps have received their promotion, subject to the required examination incident to promotion. This interpretation gives us all for which we have contended, and harmonizes very accurately with the views presented in our report at the New York meeting. In this report we incorporated the estimates of the *Army and Navy Register* relative to the number in the various grades, but those figures were understated, since we get 12 colonels instead of 9,

20 lieutenant-colonels instead of 16, and 87 majors instead of 71. In addition there will be something more than 100 first lieutenants, of which a proportionate number will be promoted to the grade of captain as soon as they have completed one year's service. This promotion on the basis of one year's service is the result of the emergency legislation for the term of the war, and was authorized by the provisions of H. R. 4897, to which bill we offered our dental amendment. In view of the fact that the Dental Corps is placed on an exact status with the Medical Corps, our corps naturally gets the benefit of this emergency legislation.

While no specific mention was made of the Dental Reserve corps in our recent legislation, my contention has always been that the

legislation for the regular corps automatically provided the authority for the necessary modification of the regulation relative to the Officers' Reserve corps to place the Dental Reserve corps on an equal status with the Medical Reserve corps. This position has been thoroughly verified by the official interpretation, and in the future whatever applies to the Medical Reserve corps will apply in like manner to the Dental Reserve corps.

In connection with this legislation I received hundreds of congratulatory messages, consisting of letters, resolutions, telegrams, and cablegrams. These were received at a time when it was impossible to give them anything like the prompt individual attention they merited. Then followed weeks of conflicting reports, but now that this matter has been officially and satisfactorily interpreted, I take this belated and public method of kindly thanking all for their generous expressions.

Fraternally,

HOMER C. BROWN, *Chairman,*

Legislative Committee, N. D. A.

609 Hartman Bldg., Columbus, Ohio.

[We are informed that the above bill in its present form does not fully meet the requirements of the Navy Department, and that other legislation involving the principle of equality of status for the Medical and Dental corps is under consideration.—ED.]

Physical Examination of Registrants in the Army.

REVISION OF THE DENTAL REQUIREMENTS.

On the recommendation of the Surgeon-general, a board consisting of Col. George E. Bushnell, U. S. Army, retired; Lieut.-cols. Thomas L. Rhoads and Philip W. Huntington, M.C.; Majors Pearce Bailey, Joseph C. Bloodgood, Elliot C. Brackett, William H. Logan, Warfield R. Longcope, Walter R. Parker, and Charles W. Richardson, M.R.C.; Contract Surg. Henry H. Morton, U. S. Army—alternate, Contract Surg. William A. Pusey, U. S. Army—was appointed to revise that section of the selective service regulations governing the physical examination of registrants. As a result of the deliberations of the board many changes have been made in the regulations. They consist chiefly of defining certain standards for unconditional acceptance or unconditional rejection by the local boards.

One of the chief reasons for defining such standards is that the selective service law permits the acceptance of registrants for special duties. These registrants who have not the physical qualifications for general military service may be otherwise physically and mentally qualified for special military service. Under the new regulations, physicians of the local boards are not required to make a complete examination of every registrant before rejection. They are required to make a complete physical examination before unconditional acceptance, and even then the registrant may appeal to the medical advisory board for a second examination. The result of the new regulations is practically to throw the large burden of the examinations on the medical advisory boards. In other words, the wholly normal or markedly abnormal, which constitute the smallest number of men in general, come within the purview of final action by the local board. All others are referred to the medical advisory boards.

The section relating to dental requirements as revised is as follows:

SECTION 185—*Dental requirements.*

Accept registrants who have three serviceable natural masticating teeth above and three below opposing, and three serviceable natural incisors above and three below opposing. All these teeth must be so opposed as to serve the purpose of incision and mastication. Therefore the registrant shall have a minimum total of six masticating teeth and a minimum total of six incisor teeth.

The needed dental treatment will be performed at the cantonment. However, if time permits, a registrant, if he prefers, may have the necessary work done at home previous to his induction into military service.

Definitions. (a) The term "masticating teeth" includes molar and bicuspid teeth, and the term "incisors" includes incisor and cuspid teeth.

(b) A natural tooth which is carious (one with a cavity), which can be restored by filling, is to be considered as a natural serviceable tooth.

(c) Teeth which are restored by crowns or dummies attached to fixed bridge work, when well placed, shall be considered as serviceable natural teeth, when the history and the appearance of these teeth is such as to clearly warrant such assumption.

(d) A tooth is not to be considered a serviceable natural tooth when it is involved with excessively deep pyorrhea pockets, or when its root-end is involved with a known infec-

tion that has or has not an evacuating sinus discharging through the mucous membrane or skin.

Refer all other cases to the medical advisory board.

No registrants can be rejected on account of teeth defects.

—From *Journ. Amer. Med. Association*.

Dental Officers' Promotions.

RESERVE CORPS.

IN accordance with orders issued some days ago, boards of officers are in session for the examination of members of the dental corps of the regular army who have had at least one year's service, to the grades of colonel, lieutenant-colonel, and major, as authorized by recent legislation. Now that these preliminary arrangements for advancement of members of the regular corps are out of the way, the matter of promotion in the dental reserve corps has been taken up, and the Surgeon-general has directed chief surgeons of divisions and departments and of the troops in France to make recommendations as to those reserve dentists of their organizations that they consider to merit advancement in rank. For the present no dental reservist will be considered for promotion unless he has been in the actual practice of dentistry for at least three years, and later none of less experience will be considered until after completion of one year's service in the military establishment during the present war. Moreover, dental reservists not on active duty will not be considered for promotion. The dental reserve corps will have the same grades as the medical reserve corps, that is, the personnel will be distributed among the grades of major, captain, and first lieutenant, those on active duty being distributed in the grades in the same proportion as in the medical branch. Thus not more than about 32 per cent. may be in the grade of major, and the remainder in the grades of captain and first lieutenant, but it is not intended completely to fill the grade of major immediately. Accordingly, of the 1500 dental reservists on active duty not more than about 484 of them may be advanced to the grade of major.—*Army and Navy Register*.

Medical Corps Instruction Extended.

IN order to equip officers and men in the special work required of the Medical corps and its sanitary, dental, and veterinary branches, extensions are being arranged for medical camps at Fort Oglethorpe, Ga., and Fort Riley, Kan. There are at present 5400 officers and men under training at Fort Ogle-

thorpe, and 3800 at Fort Riley. Fort Riley has a capacity of 7000. Enlargement of the school at Fort Oglethorpe to the same capacity has been authorized, its present capacity being 5500. There have been graduated from medical training camps since June 1st, or are now under instruction, a total of about 9000 officers and about 20,000 enlisted men. The medical training camp at Fort Benjamin Harrison, Ind., and the one at Fort Des Moines, Iowa, for colored officers and men, which contributed to the total, have been discontinued.—*Journ. of the Amer. Med. Association*.

Army Dental Corps.

EXAMINATIONS are still in progress for the determination of the fitness for promotion of officers of the regular dental corps of the army. These examinations began on December 15th in Washington and other places. Some fifteen or sixteen officers of the corps who are on duty in the Eastern, Northeastern, and a part of the Southeastern Department have been examined in Washington.

NEW APPOINTMENTS (JANUARY 21ST).

To be FIRST LIEUTENANTS: J. G. Urban, C. S. Emmert, W. H. Siefert, S. J. Lewis, J. H. O'Reilly, F. W. Miller, J. A. Curtis, Jr., J. J. Weeks, J. L. Davis, J. H. Jaffer, A. A. Meyer, H. C. Feyler, W. F. Scheumann, A. G. McCue, Jr., C. H. Glascock, A. F. Roberts, J. N. White, H. L. Sams, G. M. Krough, W. W. Woolley, E. W. Barr, F. E. Rodriguez, W. F. Wiek, T. H. Veale, L. J. Dunn, C. R. Oman, L. A. Gould, H. A. Curtis.

APPOINTMENTS—RESERVE CORPS (FEBRUARY 2D).

To be FIRST LIEUTENANTS: Lee G. Lourie, Benjamin Feldman, Frank Cabul Bettencourt, Gordon Alden Billings, Rollo Hestwood Cheney, James S. Dailey, Joseph Hyrum Davis, Chas. Lawrence Drain, John H. Gatterdam, Roy Stuart Glass, Edmund T. Glessner, William E. Goepper, Wm. H. Hanford, Fred O. Hoedt, Benjamin F. Loveall, Francis J. McDonald, Walter L. McNamara, Thomas J. Meador, Charles W. Noel, John N. Schwab, Saxon Bird Scott, John L. Shaw, Horace I. Spare, Leo Appleton Stafford, Benjamin Bryant Todd, Sherman Aloysius White, Albert Perry Williams, George M. Boehler, Francis V. Simonton, Alvin W. Viney, Samuel S. Sharfman, Maitland V. Shaver, Arthur J. Brennan, Irvin R. McCollough, Jos. Schlund Clark, Geo. A. Bender, Geo. A. Bullard, Wm. Clinton Clayton, Gordon Chappuie, Christopher C. Vaughan, Jr., Chas. E. Wach, Karan Mack Yokeley, Henry Marshall, Harry

Finkel, John Augustus Kimball, Frank Sylvester Heer, Frank C. McAuley.

—
**ADVANCEMENTS IN RANK—ARMY DENTAL
CORPS (JANUARY 26TH).**

Under provisions of an act of October 6, 1917, advancement in rank of the following dental surgeons is announced.

To be COLONELS—with rank from October 6, 1917: Robert T. Oliver, S. Davis Boak, Franklin F. Wing, Geo. L. Mason, Frank H. Wolven, John H. Hess, William H. Chambers, Alden Carpenter, Edwin P. Tignor, John A. McAlister, Jr., Geo. H. Casaday, and Julien R. Bernheim.

To be LIEUTENANT-COLONELS—with rank from October 6, 1917: Rex H. Rhoades, George E. Stallman, George I. Gunckel, Frank P. Stone, Raymond E. Ingalls, Harold O. Scott, John R. Ames, Robert H. Mills, Frank L. K. Laflamme, Minot E. Scott, George D. Graham, Robert F. Patterson, Samuel H. Leslie, Albert R. White, Mortimer Sanderson, John H. Snapp, Wm. A. Squires, Arnett P. Matthews, John W. Seovel, Charles DeW. Dayton.

To be MAJORS—with rank from October 6, 1917: Benj. C. Warfield, Herman S. Rush, Lester C. Ogg, Harry M. Deiber, Lowell B. Wright, Walter L. Reesman, Jas. G. Morningstar, Eugene Milburn, Claudius G. Baker, Samuel J. Randall, Chas. Taintor, Don G. Moore, Oscar G. Skelton, Harlan L. Thompson, Robt. B. Tobias, Harry C. Peavey, Wm. S. Rice, Emmett P. Varvel, J. Craig King, Leigh C. Fairbank, Chas. C. Mann, Richard B. Clark, Dale E. Repp, Terry P. Bull, Raymond W. Pearson, A. J. Skillman, Donald W. Forbes, James L. P. Irwin, Thomas C. Daniels, Ben H. Sherrard, Fred'k R. Wunderlich, Wilfurth Hellman, Bruce H. Roberts, Samuel Kaufman, Lee S. Fountain, John L. Schock, Chas. W. Lewis, Gerald D. Byrne, E. Henry Valentine, Oscar P. Snyder, Wm. Mann, Jos. H. Tyler, Rex McK. McDowell, Chas. M. Taylor, Thos. L. Smith, Elbert E. Rushing, Earp T. Diekmann, Walter S. Smith, Brantley I. Newsom, George R. Tressel, Lee B. Schrader, Frederic H. Bockoven, Aaron F. Eidenmiller, and Howard L. Benedict.

—
Assignments.

Army Dental Corps.

Week ending January 19th.

1st Lieut. Wm. A. Moore from duty at Fort Riley to Fort Bliss, Tex., for duty with 18th field artillery.

1st Lieut. Chas. H. Brammell from duty at Fort Riley to Douglas, Ariz., 10th field artillery, for duty.

1st Lieut. Milton A. Price from present duties and assigned with aviation section, Greenville, S. C., Camp Sevier.

The following from duty in Panama Canal department to United States and report for orders: 1st Lieuts. Chas. C. Mann and A. J. Skillman.

The following from duty at Camp Lewis, Wash., to San Francisco, Cal., to Philippine Islands for duty: 1st Lieuts. John C. Campbell and Leland S. Wilson.

Week ending January 26th.

1st Lieut. Clement J. Gaynor from duty at Camp Funston, Kan., to Jefferson Barracks for duty.

Col. Wm. H. Chambers from duty at Presidio of San Francisco, and report to commanding general, Western department, for assignment to duty.

Week ending February 2d.

Col. Julien R. Bernheim from present duties to duty in office of attending surgeon, Washington, and in addition to that duty is placed in charge of dental service of District of Columbia, exclusive of Walter Reed General Hospital.

1st Lieut. Wm. A. Moore from duty at Fort Bliss to Fort Bayard, general hospital, for duty.

Week ending February 9th.

Leave for sixty days is granted Lieut.-col. Geo. I. Gunckel on account of sickness.

—
Camp Pike Dental Society.

On January 8, 1918, the Dental Surgeons of Camp Pike organized a society, naming it "Camp Pike Dental Society." Col. John H. Hess, D.C., the division dental surgeon, was elected honorary president; 1st Lieut. Edgar T. Blocher, D.R.C., president; 1st Lieut. Henry W. Rieh, D.R.C., vice-president; 1st Lieut. George H. Elliott, D.R.C., sec'y-treasurer.

The object of the society is to increase the efficiency of the dental corps, bringing the members closer together, to broaden their knowledge along certain specific lines, mainly that of oral and war surgery. The meetings are held Tuesday evening of each week.

GEORGE H. ELLIOTT, *Sec'y-Treasurer.*

Preparedness League of American Dentists.

(Organized under the auspices of the N. D. A.)

The Dental Committee of the General Medical Board, which is the agency for the Medical and Dental Preparedness in this War-emergency has made it possible for every Dentist in the United States to assist in the work, under the supervision of
Lieut. WM. A. HECKARD, D.R.C., U.S.A., stationed at
50 East 42d st., New York, N. Y.

Circular from Director-general Dr. Chas. F. Ash.

YOU are called to SERVE YOUR COUNTRY.

If the President of the United States called on you personally and asked you to give to our soldiers and sailors at least one hour of free dental service each day, would you give it? Of course you would. He cannot call on you personally, but this is his personal appeal to you.

The President of the United States is asking you—YOU, my dear Doctor, to give your service to *help win the war*. Your part of the work must be done by *you*. No one else can do it. Every other dentist will be busy doing *his* bit. He can't do *yours*. The ships are needed to carry the fighting men and supplies. Only one dentist to every 1000 men can be taken abroad.

If we fill all the cavities and extract all the diseased teeth before our boys go to the cantonments, it will still leave more work than one dentist can do to take care of the emergencies for 1000 men.

Up to date we have a record of 136,000 operations performed, but thousands of men of our new national army have gone away

without proper dental service. This must not continue. It's up to you and me to see that this is not repeated in the future drafts.

If this work is not done it will mean *sleepless nights* for those wounded or stricken by disease.

It will mean *tripling the cost* of maintaining a man for every day he spends in the hospital.

It will mean *decreasing the efficiency* of our army and navy.

Tooth troubles are accentuated in the trenches. Would you wilfully add the horrors of abscessed teeth to the burden of injury and disease which our boys must bear?

These boys are sacrificing their home ties, many of them their limbs, and many others their lives. You are asked to sacrifice a little of your time and material each day in safe quarters with comfortable surroundings. Let us show some red blood in our veins by making this insignificant sacrifice.

Have you ever said out loud, "This is MY war"? Try it now—say aloud, "This is MY war"!

Circular from Lieut. Wm. A. Heckard.

(Detailed by the Surgeon-general's Office.)

50 EAST 42D ST., NEW YORK CITY.
January 18, 1918.

WE are engaged in war. Many of our men are now in France and many more are soon to go. It has been reported that the Germans are massing 2,000,000 more men on the French front.

The French General tells us: "Equip yourselves as if the war were going to last ten

years, but 'speed up' as if it were going to end in six months."

The President of the United States has said that every utility should be conserved and used in the great war. Dentistry is certainly a utility of the highest order. The following is quoted from two of the President's statements:

"Let us show ourselves Americans by show-

ing that we do not want to go off in separate camps or groups by ourselves, but that we want to co-operate with all other classes and all other groups in a common enterprise, which is to release the spirits of the world from bondage. . . . I will call upon all the citizens to assist local and district boards by proffering such services and such material convenience as they can offer."

Dentists have already rendered a very valuable service in performing 136,000 free dental operations—furnishing the material free, for men now in service.

Since the United States entered the war, dentistry has received additional recognition of the place it occupies among the great professions. Dentists now stand side by side with medical men and lawyers who are giving many hours of the day free to the selective service men.

A law was passed in Washington, October 6th, and signed by the President, giving dentists in the army and navy equal rank, pay, promotion, and allowances of officers of corresponding grades in the Medical corps. Same exemption of dental students as medical students. Governors have appointed dentists to serve on the medical advisory boards and exemption boards to pass on dental questions.

The dental profession is now organized to do its share of the work of speeding up preparation, and there is much yet it will have to do if it expects to maintain its newly achieved recognition.

"Under the law only one dentist per thousand is permitted in the army. One dentist to a thousand is insufficient to care

for the dental needs of the new army before it is ordered to foreign service." The Government may not recognize any special league or sets of men, but the General Medical Board, which is the agency for the medical and dental preparedness in this war emergency, through the Dental Committee, has made it possible for the dental profession to assist in this work, under the direction of the Surgeon-general's Office, and under the direct supervision of Lieut. Wm. A. Heckard, D.R.C., on active duty stationed at New York City.

We have, therefore, taken part and helped in the adoption of the military plan for organizing the Preparedness League of American Dentists, and mobilizing free dental activities, so as to simplify details and cut expense.

The French said "They shall not pass!" Let it not be said that we permitted our soldiers and sailors to leave home until dentally fit; so that when the time comes for them to "pass"—and pass they will—none will miss his chance by reason of toothache or swollen face, or worse yet, endocarditis and rheumatism from focal infection. Get in touch with your state director. Help with the job. Don't complain—help him. He may have bumps as big as yours to get over.

The Dental Committee of the General Medical Board, co-operating with the Preparedness League of American Dentists.

LIEUT. W. A. HECKARD, D.R.C.,

Detailed by the Surgeon-general's Office.

"Hurry!" was the message brought back from France by Colonel House.

Preparedness League Notes and News.

By R. OTTOLENGUI, *Publicity Committee.*

NEW MEMBERS.

The treasurer, Dr. L. M. Waugh, reports a most satisfactory response to the circular letter recently sent out as a means of recruiting members. A careful tabulation has shown that prior to January 1, 1918, there were, in round numbers, 5700 members of the League. Up to February 1st, in response to the circular letter above mentioned, 4900 new members have been enrolled, and Dr. Waugh reports that applications for membership have come in so rapidly—about a hundred a day—that

as yet it has been impossible to classify them by states. This will be reported next month.

THE LEAGUE BUTTON.

By a recently made rule, the buttons are to be sent to new members without extra charge. (Old members can get the button for 25c.) Therefore, members will please do two things: Get your button; *wear your button*. You are asked to wear it, not to advertise yourself, nor the League, but we want to make the man without a button conspicuous.

In France, within thirty days after the beginning of the war, all persons serving the Government—soldiers, hostlers, drivers, railroad men, and labor of all kinds, skilled or unskilled—wore armbands reading, "Military Service." Men without bands became very conspicuous, and received scant consideration from the "Women of France." Wear your League button!

All dentists who have not yet filled out Form 3A are requested to do so at once and mail the same to Lieut. Heckard.

DENTAL ANESTHETISTS WANTED.

My dear Dr. Ash,—I am just in receipt of one of your circulars of the Preparedness League of American Dentists, and would sign up and return cards only I am a physician and surgeon, and I am furthermore disabled with arthritis from actively participating in your efforts.

However, despite my disability and the limitations of a wheel-chair, I am co-operating with the Surgeon-general and Council of National Defense in recruiting expert anesthetists for immediate service at the front in the base hospitals and casualty clearing stations.

In this recruiting we have not drawn any lines between the surgical and dental anesthetist, believing that both are fully competent for this service. The Interstate Association of Anesthetists, of which I am secretary, has welded the interests of the medical and dental professions so thoroughly that recently in Ohio our Attorney-general, in an opinion, delegated equal privileges to medical and dental anesthetists. We are anxious to have the verdict of the war hospitals indorse this amalgamation.

It has been with some difficulty that we have persuaded the Surgeon-general that anesthetists, surgical and dental, are in great demand at the front. To emphasize their value Captain Gwathmey, of the Lakeside unit, which was loaned to the British army, during the attack on the Messines Ridge kept three surgeons busy and standing at the head of three tables radiating like spokes of a wheel, put 34 wounded soldiers under anesthesia during a period of five and one-half hours. Truly a record, and showing what the expert anesthetist can do in limiting the horrors of war.

The German, French, and even the English anesthetic service collapsed promptly at the outset of the war, and thousands of wounded were operated on without anesthesia, agents and administrators both being lacking. We are trying to avoid such a collapse of our surgical and dental service.

In this connection, if in your canvass you encounter any dental anesthetists who desire active service, or who will accept anesthetic service at base hospitals at home, or are competent to act as instructors, or in replacing those in hospitals who have lost staff anesthetist to active service, let me have their names and addresses, and I will see that they are given their chance of doing their bit.

Appreciating the efforts you are making and wishing you every success, I remain,

Cordially yours,

Avon Lake, Ohio. F. H. McMECHAN.

DENTISTS ON MEDICAL ADVISORY BOARDS.

The Government has established a new and improved system of dealing with men who claim exemption because of alleged physical defects. What are known as "medical advisory boards" have been formed, to which a man may appeal from the decision of a local exemption board, or to which the local board may refer doubtful cases. These boards, for convenience, are located mainly in conjunction with hospitals, and include high-grade and skilled medical specialists.

Dentists have likewise been appointed to all of these boards. This is a recognition by the Government undoubtedly due to the services which have been rendered by the Preparedness League.

DENTAL PERSONNEL ON THE BOARDS.

The majority of the dentists appointed on the medical advisory boards are already members of the League. However, state directors are requested to obtain the list of such appointments, and if they find thereon any who are not members of the League, a personal letter will probably induce such men to join with us.

EXEMPTIONS FOR DENTAL DEFECTS.

From early indications the dental members of the medical advisory board will have ample work to do. These boards not only examine cases of appeal, but also those cases where the local board examiners are in any doubt as to the physical disability of the registrant. The men are then classified as: "For general military service," "For limited military service," or "exempt."

There has been a disposition on the part of the local boards to shift the responsibility for the dental cases, which will be partly overcome by the presence of dentists on these boards, otherwise the present number of dentists on the advisory boards will be inadequate.

The "selective service regulations" admit of the broadest construction, and if taken literally, indicate that no man need be exempted because of defective or missing teeth.

DENTAL REQUIREMENTS.

The person must have at least eight *serviceable natural masticating teeth*, either bicuspids or molars, four above and four below opposing, and six *serviceable natural incisors* or canines, three above and three below opposing. These teeth must be so opposed as to serve the purposes of incision and mastication. There must be one molar above and one below on one side which occlude; the remaining six opposing masticating teeth may be either bicuspids or molars.

Teeth restored by crown or fixed bridge work, when such work is well placed and thoroughly serviceable, are to be considered as *serviceable natural teeth* within the meaning of the above paragraph.

A well-fitting artificial denture, plate, or removable bridge is allowed to take the place of missing teeth, providing the *serviceable natural teeth* on one side of the mouth are sufficient to meet one-half the masticating (bicuspid or molar) requirements fixed above as the minimum.

If dental work will restore the teeth so as to meet the requirements outlined in the preceding paragraphs, the man should be accepted and sent to his cantonment, where the dental work needed to bring him within the requirements will be carried out.

DIFFICULTY OF INTERPRETATION.

Observe that in one place the regulation says that well-fitting artificial teeth may take the place of natural teeth, provided that the natural teeth on one side of the mouth could sustain half the requirements of mastication. This is a little difficult to construe, especially as artificial teeth attached on one side alone constitute a more difficult problem in construction than where attachment may be made on both sides.

The last paragraph of the regulation provides that if artificial teeth would bring the man within the requirements of the original standard he may be accepted and sent to his cantonment and the work will be done there.

Already the medical members of the advisory boards are construing this to mean that if artificial teeth can be made for a man, he may be accepted. If this be the meaning, then dental examination becomes useless, because artificial teeth can be made for practically any man.

A closer study of the requirement, however, would seem to mean that *only one-half of a man's masticating apparatus may be restored by artificial teeth*. But if this is meant, the wording of the rule is unfortunate, since it seems to require that the restoration may only occur when the deficiency is on one side, which describes the least useful type of denture.

However, this is not the place to discuss this matter. It is mentioned here merely that the League may give the question intelligent study.

ORGANIZATION OF DENTAL MEMBERS OF BOARDS.

In New York City it has been decided, unless objections are made by the authorities, to form an association of the dental members of the medical advisory boards. The first meeting will occur on February 18th. Members of the Adjutant-general's staff will be present to give the dentists instructions as to the interpretation of the regulations. The final decision on some of the ambiguous features will be published next month for the information of all League members officiating on medical advisory boards.

LOCAL EXEMPTION BOARDS.

The Government will probably appoint at least one dentist on every local exemption board in the country. If League members would serve on these boards, it would greatly facilitate the League's work, as in most cases the conscripted man could be directed at once as to where he could have his dental defects treated. Therefore directors of states are urged to scrutinize all appointments to local exemption boards, and to enroll all non-members within our ranks as rapidly as possible. It is desirable to appeal to the Adjutant-general of your state and urge him to secure nomination for these boards through the presidents and officers of local boards.

SPECIAL NOTICE.

Call for Reports of Accidents from Local Anesthetics.

THERAPEUTIC RESEARCH COMMITTEE OF THE COUNCIL ON PHARMACY AND
CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION.

[From *Journal of the American Medical Association*.]

THE Committee on Therapeutic Research of the Council on Pharmacy and Chemistry of the American Medical Association has undertaken a study of the accidents following the clinical use of local anesthetics, especially those following ordinary therapeutic doses. It is hoped that this study may lead to a better understanding of the cause of such accidents and consequently to methods of avoiding them, or, at least, of treating them successfully when they occur.

It is becoming apparent that several of the local anesthetics, if not all of those in general use, are prone to cause death or symptoms of severe poisoning in a small percentage of those cases in which the dose used has been hitherto considered quite safe.

The infrequent occurrence of these accidents and their production by relatively small doses point to a peculiar hypersensitiveness on the part of those in whom the accidents occur. The data necessary for a study of these accidents are at present wholly insufficient, especially since the symptoms described in most of the cases are quite different from those commonly observed in animals even after the administration of toxic but not fatal doses.

Such accidents are seldom reported in detail in the medical literature, partly because physicians and dentists fear that they may be held to blame should they report them, partly, perhaps, because they have failed to appreciate the importance of the matter from the standpoint of the protection of the public.

It is evident that a broader view should prevail, and that physicians should be informed regarding the conditions under which such accidents occur, in order that they may be avoided. It is also evident that the best protection against such unjust accusations and the best means of preventing such accidents consist in the publication of careful detailed records when they have occurred, with the attending circumstances. These

should be reported in the medical or dental journals when possible; but when, for any reason, this seems undesirable, a confidential report may be filed with Dr. R. A. Hatcher, 414 East Twenty-sixth st., New York City, who has been appointed by the committee to collect this information.

If desired, such reports will be considered strictly confidential so far as the name of the patient and that of the medical attendant are concerned, and such information will be used solely as a means of studying the problem of toxicity of this class of agents, unless permission is given to use the name.

All available facts, both public and private, should be included in these reports, but the following data are especially to be desired in those cases in which more detailed reports cannot be made:

The age, sex, and general history of the patient should be given in as great detail as possible. The state of the nervous system appears to be of especial importance. The dosage employed should be stated as accurately as possible; also the concentration of the solution employed, the site of the injection (whether intramuscular, perineural, or strictly subcutaneous), and whether applied to the mouth, nose, or other part of the body. The possibility of an injection having been made into a small vein during intramuscular injection or into the gums should be considered. In such cases the action begins almost at once, that is, within a few seconds.

The previous condition of the heart and respiration should be reported if possible, and of course the effects of the drug on the heart and respiration, as well as the duration of the symptoms, should be recorded. If antidotes are employed, their nature and dosage should be stated, together with the character and time of appearance of the effects induced by the antidotes. It is important to state whether antidotes were administered orally, or by subcutaneous, intramuscular, or intravenous in-

jection, and the concentration in which such antidotes were used.

While such detailed information, together with any other available data, are desirable, it is not to be understood that the inability to supply such details should prevent the publication of reports of poisoning, however meager the data, so long as accuracy is observed.

The committee urges on all anesthetists, surgeons, physicians, and dentists the making of such reports as a public duty; it asks that they read this appeal with special attention to the character of observations desired.

TORALD SOLLMANN, *Chairman*,
R. A. HATCHER, *Special Referee*.

SOCIETY NOTES AND ANNOUNCEMENTS

Coming Dental Society Meetings.

National.

NATIONAL DENTAL ASSOCIATION. Chicago. August 5th to 9th.

NATIONAL ASSOCIATION OF DENTAL FACULTIES. Chicago.

NATIONAL ASSOCIATION OF DENTAL EXAMINERS. Chicago.

Xi Psi Phi Fraternity. Chicago.

ASSOCIATION OF MILITARY DENTAL SURGEONS. Chicago.

State Meetings.

SOUTH CAROLINA BOARD OF EXAMINERS. Columbia. June 24th.

Dental Library Association.

BELIEVING that one of the most important functions of a dental library is the interchange and exchange of dental books and journals, it has been thought advisable by a great many dental librarians to form a Dental Library Association, similar to the Medical Library Association.

Object: The fostering of dental libraries and the maintenance of a system for exchange of dental literature and duplicates; securing and distributing the Transactions of dental societies.

Eligible for membership: Any dental society, association, university, college, or library having a fixed home and a dental library; any individual interested in dental literature or libraries.

Benefits: The banding together of a united body, with a common cause; the betterment of conditions in dental libraries; a clearing-house through which books, journals, reprints, or lists of these, may be sent from one library to another.

We desire to know what libraries now exist, and how many would be interested in the formation of such a society.

The undersigned may be addressed as Librarian First District Dental Society, at N. Y. Academy of Medicine, or as below.

DR. B. W. WEINBERGER,
40 E. 41st st., New York City.

Vermont State Dental Society.

THE forty-second annual meeting of the Vermont State Dental Society will be held at the New Sherwood Hotel, Burlington, Vt., on March 20, 21, and 22, 1918.

PHILIP E. MELLEN, *Sec'y*,
Middlebury, Vt.

Kansas State Dental Association.

THE annual meeting of the Kansas State Dental Association will be at Topeka, Kans., on April 15, 16, and 17, 1918.

C. K. WEAVER, *Sec'y*,
Clay Center, Kans.

Missouri State Dental Association.

THE fifty-third annual meeting of the Missouri State Dental Association will be held at Columbia, Mo., April 1, 2, and 3, 1918. A splendid program is in preparation, and great things may be expected.

J. F. WALLACE, *Sec'y*,
Canton, Mo.

Texas State Dental Society.

THE thirty-eighth annual convention of the Texas State Dental Society will be held at San Antonio, Texas, the famous City of the Alamo, April 10, 11, and 12, 1918. Members of other state societies are cordially invited to attend.

J. G. FIFE, *Sec'y*,
736 Wilson Bldg., Dallas, Texas.

Michigan State Dental Society.

THE sixty-second annual meeting of the Michigan State Dental Society will be held at the Hotel Statler, Detroit, Mich., the week of April 8 to 13, 1918. The regular meeting will be held on April 8th and 9th, with a splendid program. The remainder of the week will be a postgraduate meeting, in charge of the Detroit Club Clinic, at which every important branch of dentistry will be covered.

C. G. BATES, *Sec'y*,
Durand, Mich.

Odontological Society of Western Pennsylvania.

THE thirty-seventh annual meeting of the Odontological Society of Western Pennsylvania will be held in the Hotel Chatham, Penn ave. and Fourth st., Pittsburgh, Pa., Tuesday and Wednesday, April 9 and 10, 1918.

The Program Committee promises one of the best dental meetings ever held. Men of note will read papers of interest to the twentieth-century dentist.

The clinics will be given by the study clubs of Western Pennsylvania, and will be of interest to one and all.

Exhibitors will be amply accommodated with space by addressing Dr. Leslie Waddill, Jenkins Arcade Bldg., Pittsburgh, Pa.

KING S. PERRY, *Sec'y*,
719 Jenkins Bldg., Pittsburgh, Pa.

Ontario Dental Society.

THE fifty-first annual meeting of the Ontario Dental Society will be held in Toronto, Canada, April 29th to May 2d.

J. P. MACLACHLAN, *Sec'y*,
26 College st., Toronto, Can.

Connecticut State Dental Association.

THE fifty-fourth annual meeting of the Connecticut State Dental Association will be held at the Hotel Taft, New Haven, Conn., April 18, 19, and 20, 1918.

GEO. S. B. LEONARD, *Sec'y*.

Virginia State Dental Association.

CHANGE OF DATE OF MEETING.

THE Virginia State Dental Association will meet in Roanoke, Va., April 29 and 30, and May 1, 1918.

F. R. TALLEY, *Corr. Sec'y*,
Petersburg, Va.

Illinois State Dental Society.

THE fifty-fourth annual meeting of the Illinois State Dental Society will be held at Bloomington, Ill., May 14, 15, 16, and 17, 1918.

J. E. HINKINS, *President*,
Chicago, Ill.

J. P. LUTHINGER, *Sec'y*,
Peoria, Ill.

Iowa State Dental Society.

THE fifty-sixth annual meeting of the Iowa State Dental Society will be held in Des Moines, Iowa, May 7, 8, and 9, 1918. An excellent program has been prepared, including seminars, papers, and clinics. A cordial invitation is extended ethical members of the profession from out of the state to attend any or all of these sessions.

E. R. SWANK, *Sec'y*,
Panora, Iowa.

Kentucky State Dental Association.

THE next annual meeting of the Kentucky State Dental Association will be held at Lexington, Ky., June 13, 14, and 15, 1918. An "amalgam program" of special interest.

Address all correspondence to

W. M. RANDALL, *Sec'y*,
1035 Second st., Louisville, Ky.

Pennsylvania State Dental Society.

THE golden anniversary meeting of the Pennsylvania State Dental Society will be held in Wilkes-Barre, April 23, 24, 25, and 26, 1918. Excellent talent has been secured for the occasion and the program extended to a four days' session. To judge by preliminary reports of committees, this event promises to be the greatest meeting in the history of this organization. All ethical practitioners are cordially invited to attend.

J. F. BIDDLE, *Sec'y*,
517 Arch st., Pittsburgh, Pa.

South Carolina State Dental Association.

THE annual meeting of the South Carolina State Dental Association will be held at the Jefferson Hotel, Columbia, S. C., June 27, 28, and 29, 1918.

W. BUSEY SIMMONS, *President*,
ERNEST C. DYE, *Sec'y*.

Dental Society of the State of New York.

THE fiftieth anniversary of the Dental Society of the State of New York will be held at Saratoga Springs, N. Y., June 13, 14, and 15, 1918. The society will endeavor to present a literary, clinic, and social program for the benefit of the profession, in keeping with its golden anniversary. A cordial invitation is extended to all members of the National Dental Association. For further information write

A. P. BURKHART, *Sec'y*,
52 Genesee st., Auburn, N. Y.

Northwestern University Dental School.

ALUMNI ASSOCIATION CLINIC.

THE Northwestern University Dental School Alumni Association will hold the Annual Home-coming Clinic, 31 W. Lake st., Chicago, Ill., on June 10 and 11, 1918. Special features have been provided which will insure a successful and interesting meeting. Make your arrangements now to be in attendance. For information address

M. M. PRINTZ, *Sec'y*,
4235 Lake Park ave., Chicago.

North Carolina Dental Society.

THE North Carolina Dental Society will meet on June 19 to 21, 1918. Headquarters, Oceanic Hotel, Wilmington, N. C.

W. T. MARTIN, *Sec'y*.

California State Dental Association.

THE California State Dental Association will hold its regular annual session for the year 1918 in San Francisco, July 8 to 13, 1918.

We will conduct our meeting this year on the Oklahoma plan, and feel that we can assure all who attend a pleasant as well as a profitable meeting. Further information may be obtained by addressing

JOHN E. GURLEY, *Sec'y*,
350 Post st., San Francisco.

New Jersey State Dental Society.

THE forty-eighth annual convention of the New Jersey State Dental Society will be held on July 17, 18, and 19, 1918, on Young's Million Dollar Pier, Atlantic City, N. J.

The entire convention will be held on the pier. Machinery Hall will be used for the exhibits. Those who attended last year will remember the magnificent display of dental goods, and Dr. S. I. Callahan of Woodstown, N. J., chairman of the Exhibit Committee, with 25,000 square feet of space available, has promised an exhibit greater than that of 1917.

Machinery Hall extension, with 10,000 square feet of space, will give ample room for clinics. Dr. Edward Stillwell of Glen Ridge, N. J., is chairman of the Clinic Committee, and has already arranged for a number of new and interesting clinics. This section will be of special interest.

The Essay Committee, under the direction of Dr. C. M. F. Egel of Westfield, will present two or three essayists of prominence whose names and subjects will be announced later.

All meetings for the presentation of papers as well as the business meetings will be held in the Greek Temple. This is a delightfully cool spot half-way out on the pier.

The headquarters of the society will be at the pier entrance. Mail may be directed to exhibitors, clinicians, or members in care of the secretary, New Jersey State Dental So-

cety, Young's Million Dollar Pier, Atlantic City, N. J.

A list of hotels where special rates may be secured will be published in the *New Jersey Dental Journal* prior to the convention, or may be secured by addressing the secretary.

A cordial invitation is extended to ethical practitioners.

JOHN C. FORSYTH, *Sec'y*,
430 E. State st., Trenton, N. J.

Western Fairfield County (Conn.) Dental Society.

UNDER the above name the dentists of Stamford, Norwalk, Greenwich, New Canaan, and Darien have organized a new dental society.

The officers are as follows—J. D. Hertz, Stamford, president; Wm. L. Weed, Norwalk, vice-president; O. T. Rule, Stamford, secretary; R. G. Collins, Greenwich, treasurer.

O. T. RULE, *Sec'y*,
Stamford, Conn.

Forsyth Training School for Dental Hygienists.

ALUMNÆ ASSOCIATION.

THE Alumnæ Association of the Forsyth Training School for Dental Hygienists, Boston, Mass., held its first meeting at the Forsyth Dental Infirmary for Children on January 15, 1918. Dr. E. C. Briggs was the speaker of the evening. His interesting speech was greatly enjoyed by all present. Dr. Harold DeW. Cross, director of the Forsyth Dental Infirmary for Children, also addressed the alumnæ, and made some helpful suggestions.

MISS KEENAN, *Sec'y*,
Foxboro, Mass.

New Jersey Board of Registration.

THE State Board of Registration and Examination in Dentistry of New Jersey will hold their annual meeting and examination in the Assembly chamber, at the State-house, Trenton, N. J., on June 24, 25, 26, 27, and 28, 1918. License fee \$25, re-examination fee \$10.

Attention is directed to the following quotation from the dental law of New Jersey: "Applicant shall present to said board a

certificate from the commissioner of education of this state, showing that before entering a dental college he or she had obtained an academic education consisting of a four-year course of study in an approved public or private high school, or the equivalent thereof." In accordance with this law the secretary will issue application blanks only upon presentation of the required certificate from the commissioner of education, State-house, Trenton, N. J.

Applications must be filed complete ten days before the date of the examinations. Address all communications for further particulars to

JOHN C. FORSYTH, *Sec'y*,
430 E. State st., Trenton N. J.

Indiana Board of Examiners.

THE next meeting of the Indiana State Board of Dental Examiners will be held at the State-house, Indianapolis, June 17 to 22 inclusive. Applications and other information may be obtained by addressing

H. C. MCKITTRICK, *Sec'y*,
Indianapolis, Ind.

South Carolina Board of Examiners.

THE annual meeting of the South Carolina Board of Dental Examiners will be held at The Jefferson, Columbia, S. C., beginning promptly at 9 o'clock, Monday morning, June 24, 1918.

All applications must be in the hands of the secretary by June 14th. Application blanks and full information may be obtained by addressing

R. L. SPENCER, *Sec'y*,
Bennettsville, S. C.

Mississippi Board of Examiners.

THE Mississippi Board of Dental Examiners will hold its next annual meeting at the State Capitol building in Jackson, on the third Tuesday in June 1918, at 8 A.M. Fee for examination \$10. Practical and written examinations. Diploma from recognized school and certificate of moral character required. No reciprocity or interchange. For further information, address

B. J. MARSHALL, *Sec'y*,
Marks, Miss.

ORIGINAL COMMUNICATIONS

The Relationship of Oral Secretions to Dental Caries:

III. Ferments of Human Saliva Other Than Amylase.

By HERMANN PRINZ, D.D.S., M.D., Philadelphia, Pa.

From the Laboratory of Pharmacology, Evans Institute, Univ. Pennsylvania.

(Continued from page 203.)

FOR some time past it has been known that human saliva is endowed with biochemical properties other than the mere saccharification of cooked starch into maltose by its amylase content, and that these facts strongly point to the possible presence of other ferments. An analysis of the salivary glands of the ox by Rosell revealed the presence of five intracellular ferments, *i.e.* amylase, aldehydase, indo-phenol oxydase, catalase, and trypsin. The writer has made numerous attempts to isolate and if possible disclose the dynamics of the various ferments present in human saliva, and he succeeded in definitely verifying the existence of amylase, maltase, catalase, and oxydase. To detect trypsin, which is claimed by some investigators to be present in human saliva, the very sensitive casein-acetic acid reaction of Michaelis was applied, but not even the

minutest trace of this ferment could be revealed.

Ferments, according to Abderhalden, may, in general, be divided into two main groups, viz, the hydrolytic and the oxidizing ferments. The former may be further subdivided according to the material to be attacked, into (a) ferments which effect the decomposition of the carbohydrates, *i.e.* carbohydrases, (b) the proteolytic ferments which act upon the proteins, *i.e.* proteases, and (c) the fat-splitting ferments, *i.e.* lipases.

According to the above grouping, the ferments of human saliva are represented by the carbohydrase group of the hydrolytic enzymes and by oxidizing ferments. Proteolytic and fat-splitting ferments so far have not been observed in the normal secretions of the oral cavity. Amylase, and to a much less extent maltase, are the principal carbohydrases, while oxy-

dase and catalase typify the oxidizing ferments of human saliva. The representatives of this latter group are accredited with being the oxygen-carriers of the living tissue cell, that is, are catalytic agents which by their mere presence, even in the very minute quantities and without losing their identity, cause an indefinite amount of oxidation. These ferments are known as oxydases. The resultant peroxids of the oxydase activities are, in turn, acted upon by an additional group of ferments which by their catalytic properties reduce these peroxids with the evolution of oxygen. They are known as catalases.

The properties and dynamics of amylase have been discussed in previous papers (see DENTAL COSMOS issues for February and March). Maltase, sometimes referred to as glucodase, is a ferment which is widely distributed in the animal and vegetable kingdoms. From animal tissues it has been isolated from the salivary glands, the liver, the pancreas, etc., while in the vegetable kingdom malt and yeast are extremely rich in this enzyme. The principal function of maltase consists in splitting one molecule of maltose into two molecules of glucose.

In human saliva, very small quantities of maltase usually accompany the amylase, as was first pointed out by Von Mering. Neilson and Sheele contend that the rise and fall of the amylase index is proportionally shared by that of the maltase index. There seems to exist a close interdependence between the quantities of the various ferments, which as we have observed is apparently participated in by all the salivary ferments.

As we have mentioned above, the process of oxidation and reduction as occurring in the living cells depends upon the presence of substances which combine loosely the free oxygen at a comparatively low temperature, and which are capable of giving off their oxygen to dioxidizable substances, such as our foodstuffs. These agents are ferments, and as they are capable of changing their function repeatedly, they are referred to as reversible enzymes. As a matter of

fact, all enzyme action is reversible. But not merely the metabolic changes as occurring in the living cell depend upon this reversible enzyme action, but, as a sequence, the action of drugs. Pharmacologic action can only be explained upon the basis of a chemic interchange between the drug and the living protoplasm by means of these substances. These agents which carry on the never-ceasing process of oxidation and reduction are known as oxydases and catalases, and they are so closely allied in regard to their action that, as Kastle has pointed out, it may be, after all, that when examined more closely the catalases will show peroxydase reaction. As it is, the two sets of substances, if they are really distinct, are certainly found in the closest and most intimate association in both the plant and animal tissues. According to Chodat, oxydases are ferments which influence the process of oxidation in the living cell either positively or

Petrograd, in 1899, discusses the nature and function of oxydase occurring in saliva, and Smith and MacDonald of Boston, in 1911, again refer to it in response to an inquiry by Dr. H. C. Ferris regarding the presence of a germicidal agent in saliva. As we intend to consider the biological significance of human saliva relative to its general ferment content in regard to dental caries in a later communication, we wish to reserve the discussion of this phase of the subject until then.

The various tests for maltase, catalase, and oxydase as employed for the purpose under consideration are discussed in the subsequent pages. As regards maltase, the various tests employed have been, in general, unsatisfactory owing to the very small amount of this ferment present in saliva. For the catalase test we have selected the permanganate method as giving most excellent results. It is based upon the equation:

negatively; in harmony with their specific function they are divided into oxygenases, *i.e.* bodies which take up molecular oxygen to build up peroxydases, and peroxydase which materially increase the stagnant peroxids present in dilute solutions.

Catalases may be looked upon, according to Herlitzka, as agents possessing the faculty of reducing peroxids and thereby acting as protectors of the living organism. Through the decomposition of hydrogen dioxid as resultant from the peroxydase action, into water and molecular (inactive) oxygen, the living cell is protected against the injurious effects of super-oxidation. Recent experiments carried out in the physiological laboratory of the University of Illinois which point to the fact that an increase or decrease in the amount of work, and hence in oxidation, in a muscle, is accompanied by a corresponding increase and decrease in the amount of catalase, would seem to suggest that catalase may play a rôle in the oxidative processes of the body.

In his doctorate thesis, Slowtzwof

From the various tests which have been recommended for oxydase, we can vouch for good results obtained with the indophenol reaction (Röhmman-Spitzer). Smith and MacDonald claim that the color obtained with a freshly prepared 1 per cent. solution of pyrocatechin is a sufficient test for this enzyme in saliva.

TESTS FOR MALTASE.

Numerous tests for maltase are recommended in the various text-books. The minute quantities in which this ferment is present in saliva, and its frequent absence, eliminate certain tests completely, while others are applied only with difficulty. As maltase cannot be readily separated from amylase, the writer admits that in general the various tests for maltase in saliva have not been very satisfactory in his hands. The often-recommended reduction test with Barfoed's reagent for the above purposes has always failed. Polarization may be successfully employed, but rather copious quantities of the digested substratum are required,

and consequently large quantities of individual saliva. The degree of rotation of maltose hovers about $(\alpha) D, = 138^\circ$, while that of glucose equals about $(\alpha) D, = 53^\circ$. As a test for the qualitative estimation of maltase the phenyl-hydrazin test can be recommended. This test is based upon the property possessed by certain sugars to form osazones, *i.e.* definite crystalline bodies which are typical for each sugar. Maltose-azone and glucose-azone may be obtained from saliva in the following manner: A test tube containing a mixture of 10 cc. of a 1 per cent. soluble starch solution and 1 cc. of saliva is placed in a water-bath of 38° for fifteen minutes. In the bottom of a small test tube, enough to fill its rounded portion only, an intimate dry mixture of two parts of phenyl-hydrazin hydrochlorid and three parts of sodium acetate by weight is placed, to which is added 5 cc. of the digested starch solution. The mixture is thoroughly shaken and heated in the boiling water-bath for at least $1\frac{1}{2}$ hours. The viscid sediment which is frequently formed at the beginning of the test should be filtered off at once. The tube is allowed to cool slowly in the water-bath, and the resultant crystals are examined microscopically. Typical crystals of maltose-azone are readily observed and occasionally crystals of glucose-azone may be seen; the latter indicate the presence of maltase.

TEST FOR CATALASE.

Required solutions:

- (1) Saliva.
- (2) 1 per cent. solution of hydrogen dioxid.*
- (3) N/10 solution of potassium permanganate.†
- (4) $2\frac{1}{2}$ per cent. solution of sulfuric acid.

* Fifty grams of solution of hydrogen dioxid U. S. P. is diluted with 100 cc. of distilled water.

† N/10 solution of potassium permanganate for this purpose is prepared by dissolving 15.8 grams of potassium permanganate, c. p., in 1 liter of distilled water. After standing for 48 hours the solution is filtered.

One cc. of freshly secreted saliva is mixed with 5 cc. of 1 per cent. solution of hydrogen dioxid in an Erlenmeyer flask of about 50 cc. capacity, covered with a watch crystal and allowed to stand at room temperature, with frequent shaking, for two hours. Ten cc. of $2\frac{1}{2}$ per cent. sulfuric acid is now added, and the agitated mixture is at once carefully titrated with N/10 solution of potassium permanganate. At the appearance of the pink tint, which must remain unaltered for fifteen seconds, the titration is completed and the number of cc. used, read in one-tenth fractions, is noted. The control test, started simultaneously with the main test, consists of the same mixture, except that distilled water is substituted for the saliva. From 6 to 7 cc. of the permanganate solution is usually necessary to decompose the control test, H_2O_2 solution. By comparing the number of cc. of the permanganate solution required in the titration of the two tests a quotient is obtained which indicates the numerical power of the catalase present.

The problem involved in the catalase test may be stated as follows: How many cc. of N/10 $KMnO_4$ are required to decompose a mixture of a given quantity of a ferment *plus* hydrogen dioxid solution exposed within a given time to room temperature, as compared to the same quantity of hydrogen dioxid *without* the ferment employed as the standard test? The number of cc. of N/10 $KMnO_4$ required for the catalase test may be represented as CT, and that of the standard test as ST, while the assumed quantity of catalase which completely decomposes 100 cc. of 1 per cent. H_2O_2 may be arbitrarily represented by 100, or as $C(100 - x)$. Consequently the formula for the catalase index reads:

$$\frac{CT}{ST} = C(100 - x)$$

Ex. If 38 cc. of N/10 $KMnO_4$ be required to decompose 100 cc. of 1 per cent. H_2O_2 + ferment solution, and 138 cc. for the same quantity of the standard test solution, its quotient reads:

$$138 \div 38 = 27.5,$$

which when subtracted from the catalase standard, *i.e.*

$$100 - 27.5 = 72.5;$$

the latter represents the quantity per cent. of the catalase present.

The above procedure furnishes excellent comparative results. If one is interested in the exact amount of hydrogen dioxid decomposed, a freshly standardized solution of potassium permanganate, containing 0.316 per cent. of the salt, should be employed; 1 cc. of this solution corresponds to 0.002 of hydrogen dioxid.

TEST FOR OXYDASE.

Required solutions:

- (1) Saliva.
- (2) 1 per cent. alpha-naphthol solution.*
- (3) 0.75 per cent. aqueous para-phenylene-diamin solution.
- (4) 1.7 per cent. sodium carbonate solution.

One-half of one cc. of freshly secreted saliva is placed in a Petri dish 8.8 cm. in diameter, having a polished bottom. One cc. each of solutions 2, 3, and 4 are mixed in a graduated cylinder and diluted to 10 cc. with distilled water. Of this solution 5 cc. is added to the saliva, carefully mixed, covered, and allowed to stand at room temperature for one hour; then 5 cc. of 95 per cent. alcohol is added, thoroughly mixed, and allowed to stand for one-half hour. The alcohol will dissolve the freshly formed indophenol. The mixture is filtered and compared colorimetrically with a standard color solution.

The standard test color solution is prepared by mixing 3 cc. of the undiluted alkaline alpha-naphthol para-phenylenediamin solution with 50 cc. of diluted alcohol, *i.e.* equal parts of 95 per cent. alcohol and distilled water, and allowing it to rest for about three to four days, or until the maximal color of indophenol has developed. As this solution

fades readily, it must be renewed as soon as a change in the intensity of color is noted, *viz.* in about two weeks. The color of indophenol is of a deep violet-blue. A more lasting test color solution which closely matches the indophenol solution may be made by adding diluted ferric chlorid solution to an aqueous solution of salicylic acid, or by using a very diluted solution of methyl-violet-B. In the absence of an expensive colorimeter a useful home-made apparatus for this purpose may be readily constructed according to the following directions: Ten small test tubes of the same diameter and size are placed in a test-tube rack and serially numbered. Tube 1 is filled with 10 cc. of the indophenol standard solution; tube 2 receives 9 cc. of the standard test color solution and 1 cc. diluted alcohol, and the remainder of the tubes are charged in the same manner with the geometrically diluted indophenol solution. By comparing the saliva-indophenol solution, placed in a test tube of the same size as that of the test solution, with the standard color solutions, against a sheet of white paper in a good light as a background, fairly reliable comparative results are obtained.

THE SUPPOSED SUGAR CONTENT OF HUMAN SALIVA.

Blood, lymph, muscle, and other tissues of the human organism contain variable quantities of sugar. Normal human blood contains an average of from 0.06 to 0.11 per cent. of sugar. The quantity varies within limits depending primarily upon ingested foodstuffs. Under certain pathologic conditions, as in glycosuria, diabetes, uremic nephritis, etc., the quantity of sugar in the blood may be materially increased; as much as 1.11 per cent. has been recorded. The presence of sugar in the urine, especially under pathologic conditions, is so well known that it does not need to be especially emphasized. Basing our conception hypothetically upon these facts, it is, *a priori*, very alluring indeed to assume that sugar might be present in normal or in pathologic saliva, and that as a consequence this supposed sugar content may have

* 1 gram of alpha-naphthol is dissolved in 100 cc. of a mixture of equal parts of alcohol and water.

some possible bearing on the etiology of dental caries. Indeed, this conception is by no means new; numerous investigators, among whom especially Michaels and Kirk should be mentioned, have discussed this very problem. In a paper by Kirk, "A Reconsideration of the Etiology of Dental Caries, and a New Theory of Caries Susceptibility," published in the DENTAL COSMOS for January 1914, the following statement will be found:

In several communications, notably those already referred to as having been read before the Ohio State Dental Society in 1902 and before the Michigan State Society in 1913, I called attention to the probable existence of a fermentable carbohydrate substance in the saliva, the result of carbohydrate metabolism derived from the blood through the medium of the salivary glands. My attention was first directed to this matter in some studies of the saliva that I made in the laboratory with Joseph Porter Michaels in Paris in 1901. One of the routine tests made by Michaels in the examination of all specimens of saliva submitted to him was what he called the glycogen test, and I find in my notes made at the time that glycogen, according to Michaels, had been detected in the saliva by Salomon, and that other carbohydrate substances—for example, glucose—had been detected by Lecorché, Pavy, Lehmann, Jordeo, Nasse, Koch, and Gorup-Besanez, and that Arthus had determined the presence in the saliva of erythrodextrin, achroödextrin, and of maltose; and Michaels says: "I have myself determined the presence of sugar in the saliva of diabetics. Glucose takes a red coloration with Nessler's reagent, which passes into a grayish blue."

He says, further:

The difference of opinion relative to the passage of sugar into the saliva and the perspiration is explainable as follows: Sugar passes with difficulty into the saliva, and it is not apparent in appreciable quantities except in pronounced diabetics. The saliva contains large quantities of bacteria, and unless certain precautions are taken the contained sugar disappears by fermentation. The albuminous substances may interfere with the fermentation. According to Claude Bernard, cane sugar injected into the blood does not pass into the pathological saliva.

J. P. Michaels in his interesting brochure, "Sialo-semiology," states that "There is a great divergence of opinion

between authors in regard to the elimination of sugar through the sweat and saliva of diabetic patients," and enumerates these opinions as quoted by Kirk. In discussing the metabolism of diabetes mellitus, Von Noorden makes this statement:

Most researches upon the presence of sugar in the saliva have proved negative. Külz, however, quotes several observers who found it: and Fleckseder has recently reported two cases with a positive sugar reaction. F. Kraus, Jr., working in my laboratory, and using the most sensitive tests, including that of phenyl-hydrazin in each case, could find no trace of sugar in the saliva of ten severe cases who were excreting sugar in large quantities. Theoretically, one would think sugar ought to appear in the saliva sometimes, seeing that a dog's salivary glands let sugar through when 0.8 per cent. is present in the blood. Sugar values as high as this were obtained by transfusion with dextrose solution: they scarcely ever occur spontaneously in diabetes, but one would think patients would be found now and then whose salivary glands were abnormally permeable to sugar. In all researches upon the subject it is necessary to analyze the saliva fresh and pure, since reducing bodies may be derived from the decomposition of mucin. The sweet taste in the mouth that diabetic patients often complain of is probably not due to the presence of sugar, but to that of acetone.

To satisfy himself relative to the sugar content of saliva, the writer has utilized two very sensitive tests for this purpose, *i.e.* the micro-method of Ivar Bang, which allows a fair estimation of 0.02 mgm. in 100 cc. menstruum, and the micro-analysis of Bertrand as modified by Michaelis and Rona. The latter method, while somewhat complicated, is especially to be recommended for the above purpose, as it allows an accurate determination of even the minutest quantities (less than 0.02 mgm.) of glucose. In no case, even in a saliva from a diabetic patient with a known sugar content of 7 per cent. in the urine, could the faintest trace be obtained. Basing his conception on experimental data, the writer must deny the presence of sugar in human normal or pathologic saliva.

(To be continued.)

40TH AND SPRUCE STS.

Effects of Decayed Teeth upon a Child's Progress in School.

By EARLE E. JOHNSON, D.D.S., Burlington, Vt.,

DIRECTOR OF VERMONT RURAL DENTAL CLINICS.

(Read before the Bennington County Teachers' Association, Bennington, Vt., February 7, 1918.)

IT is my purpose today to present for your consideration some thoughts upon the condition of the children's teeth, and to give you an idea of the work that has been undertaken in this state by the "rural dental clinics" for the care of the children's teeth.

Vermont has the honor of establishing the first system of rural dental clinics in the country, and she may well feel proud of this fact, as it is recognized by the dental profession as the ideal method of procedure in the rural districts. The funds for the carrying out of this work were obtained through the generosity of Miss Emily Proctor and Hon. Redfield Proctor, who, realizing that the health of the child depends in a great measure upon the condition of the teeth, and appreciating the practical impossibility of the majority of the rural school children receiving dental treatment, established a fund for this purpose.

You are all more or less familiar with the plans for carrying out the work. In brief, it is to reach the rural districts that do not have access to a dentist, and to treat all of the children in these districts between the ages of six and twelve years who are in need of treatment, which will be practically *all*. This age limitation is made necessary on account of the large territory to be covered, and in view of the fact that the greatest amount of good can be accomplished between these ages.

EQUIPMENT FOR THE RURAL CLINIC.

A complete equipment consists of a car and a portable army dental unit,

which is capable of being set up in a short time and occupies a minimum amount of space. This unit can all be packed into a specially constructed box on the car, weighs about 500 pounds, and can be moved from one place to another with very little inconvenience.

This work will be done in the school-houses where possible, and will be consistent with the most advanced ideas of clinical dental pediatrics. The territory should be covered every six months, and *will be* after we have a sufficient number of men to make this possible.

While the operative procedures are very essential, the educational value of illustrated lectures, toothbrush drills, etc., is of prime importance. During these years a child's mind is very receptive and is capable of being molded and receiving impressions that would be lost upon the custom-hardened intellect of their elders. Therefore any correct hygienic principle instilled into their minds at this time will follow them through life, and will save them much suffering and disfigurement.

The physical examination of school children shows that from 95 to 99 per cent. are in need of immediate dental treatment, and the most conspicuous defect of the children is their unsanitary mouths. The children that have come under our observation average from eight to ten cavities each, usually accompanied by two or three broken-down, abscessed teeth which are continually pouring pus into the system and undermining the health of the child. Just consider for a moment what this condition means—eight or ten cavities ranging in size

from a pinhead to a total destruction of the crown of the tooth; eight or ten holes filled with rotten, decaying food, sometimes weeks old, with additional fragments lodged between many of the other teeth, constituting almost a teaspoonful of fetid matter, and they are actually mixing this decomposing mass with all the food and drink that they take.

Dr. Kirk says that this constant drain of poison into the intestinal tract in child life causes an intestinal indigestion in which bacterial products are absorbed into the system, and produce fevers, headaches, eye-strain, anemia, malaise, and constipation. Nature finally takes away the child's appetite and forces it to bed until a good house-cleaning can be accomplished. The poisons from the mouth are insidious and slow in action; many can and do withstand them for years, but as the constant dropping of water will wear away the stone, so will the products of decomposing food in the mouth soon destroy a good digestion and undermine the system.

IMPORTANCE OF CARING FOR THE TEETH OF SCHOOL CHILDREN.

It is unfortunate that the teeth of children, just at the age when thorough mastication is of greatest importance, are allowed to decay to such an extent that it becomes a painful operation for the child to masticate food at all. It is during this age that the greatest development should take place, but most of the children are dental cripples by this time. A child cannot be expected to develop into a healthy adult with a strong mind if it is deprived of efficient means of chewing its food properly, or if the food must pass through an infected and uncared-for mouth that is more like a cess-pool than a receptacle for the transmission of food to the human body, every ounce of which must pass through this disease-breeding area, and naturally becomes burdened with numerous colonies of bacteria. No wonder such children are sickly and lacking in strength to resist disease, or that they are not con-

sidered bright and intelligent, figuring many times as members of our mentally deficient class in school work. No child can grow in grace, mentality, or stature with a body that is not properly nourished, with organs seeking to grow and develop but with nothing to grow or develop on, and these are the exact conditions present in many cases.

Diseased teeth are usually aching teeth, and a child with toothache is not able to meet the requirements of our modern educational system. Eating is a process to be avoided, and it is practically impossible for the child to sleep. Weakened by the loss of sleep and the lack of nourishment, he becomes discouraged in everything that he undertakes, is lacking in ambition, and is pessimistic. His standard of self-respect and respect for his teachers and classmates is lowered, his judgment is clouded, and his ability to discriminate between right and wrong is greatly handicapped. His associates are in keeping with his lowered ideals, and we are permitting a child to start on the downward path through no fault of his own.

UNCLEAN MOUTHS A MENACE TO PUBLIC HEALTH.

Forgetting for a moment the effect that an unclean mouth has upon an individual, let us turn our attention to the result it has upon the public. Today everybody feels that the condition of their children's mouths is their own private affair. We must get away from this selfish, erroneous, and dangerous attitude, for with every breath from an unclean mouth millions of pathogenic bacteria, easily capable of inoculating another person with a virulent organism, are expelled from one to ten feet, and a filthy mouth becomes as much a public menace as the unswatted fly, filthy streets or garbage cans.

Miller claimed to have isolated about sixty kinds of bacteria from the juices and deposits in the mouth, a great many of which were disease-producing.

The mouth is an ideal incubator, for here we find all of the essentials for

the propagation and development of these organisms—the right temperature, sufficient moisture, darkness, and a menu to choose from that would tempt any member of this large family.

An unclean mouth means an increased number of bacteria, and with increased numbers come increased dangers from infection. The bacteria which cause tuberculosis, pneumonia, measles, scarlet fever, diphtheria, erysipelas, influenza, cerebro-spinal meningitis, and many other diseases, have the mouth as their happy hunting-ground, and are ready to set up their specific disease whenever the bodily resistance becomes lowered.

Children with defective teeth are more susceptible to all contagious diseases, and are apt to pass them on by means of borrowed pencils, rulers, and handkerchiefs, making the condition of their mouths one of concern to all parents.

During an epidemic of scarlet fever in Chicago those affected were of course sent away, quarantined, and the other usual precautions taken, and were not allowed to return to school until well. Their return was frequently followed by a fresh outbreak of the disease, the cause of which could not be determined for a long time. After the enforcement of a regulation requiring each child having the disease to have the mouth cleaned and every cavity in the teeth filled before returning to school, the epidemic was stopped. Similar results were also obtained at St. Vincent's Orphan Asylum in Boston. The average number of contagious diseases in that institution was about 100; this was reduced to two cases after the establishment of a dental infirmary. These illustrations show what can be accomplished by proper dental attention, and since it is the state that has to pay so dearly for these epidemics, the condition of the child's mouth should be one of interest to all.

ECONOMIC VALUE OF CLEAN MOUTHS TO THE COMMUNITY.

In Cleveland, Ohio, 97 per cent. of the school children had defective mouths. In the prosecution of the clinical work

to improve the mouth conditions twenty-seven of the children selected as having the greatest amount of oral defects in a school of 846 pupils showed after proper dental attention an average increase in their efficiency in school work of 99.8 per cent. This was apparently due wholly to the correction of their oral conditions and teaching them the proper care and use of their mouths. The improvement in their physical and moral standards was quite as marked as that in their mental activity. These results are in keeping with other statistics in this field, and we could produce similar results in every community. Every school has a certain percentage of retarded pupils, pupils who have failed to pass to higher grades. The cost of having the child make up this work amounts to millions of dollars throughout the country, a large percentage of which could be saved by giving the children proper dental attention. Two or more decayed molars will keep a child back six months in school during the first eight grades, which means an extra cost of from \$25 to \$50. In New York City a few years ago 67,000 children failed to be promoted to higher grades because of absence, 80 per cent. of which was laid either directly or indirectly to defective teeth, costing the city of New York \$1,037,696. It has been clearly demonstrated that the worse the condition of the teeth, the worse the school standing of the child.

You have seen scores of pupils absent from school on account of the toothache, and you realize that the anemic, ill-nourished, stupid, retarded child is almost always one with a foul, unclean mouth. "What is the use," says a noted educator, "of trying to teach arithmetic to a child whose capabilities are only half their maximum, due to a grossly neglected oral cavity."

When you see a child who is from one to three years behind his proper grade, is pale, listless, apathetic, gives a history of headaches, and is unable to cope with his studies, you can take it for granted that you will find upon examination actually repulsive conditions of the mouth.

These unfortunates are being deprived of this measure of education, besides endangering the health of other children by reason of their susceptibility to infectious disease, simply because the public does not realize that the condition of the child's mouth is a part of their business, and does not insist upon having this condition remedied.

DR. OSLER ON DEFECTIVE TEETH.

Dr. Osler, the noted physician, says, "If I were asked to say whether more physical deterioration was produced by alcohol or defective teeth, I should unhesitatingly say, Defective teeth." which is the light in which it is viewed by the medical profession at the present time.

Taking, then, this specific knowledge as to the deleterious effect of a diseased mouth upon the child, school, state, and nation, into consideration, it becomes a great economic and sociological problem that should appeal in the highest degree

to all teachers who are interested in the welfare of the child.

Summing up, then, oral cleanliness means less disease. It means fewer physicians' and dentists' bills. It means more work and play and less discomfort and pain. It means more attractiveness and greater self-respect, more aggressiveness and greater initiative, more of the rose-tint of health and less of the wanness of disease. It means stronger bodies and brighter minds, greater vitality and less physical and moral insufficiency and renders the child better able to choose between right and wrong.

In conclusion, to say that most of the ills of the human family are due to the lack of proper care during the period of childhood is not saying more than is generally conceded by those who are most competent to judge; and statistics show that the teeth are directly or indirectly responsible for from 80 to 90 per cent. of all these ills.

Vincent's Angina from the Oral Surgical Standpoint.

By HARRY A. HAINES, D.D.S., Philadelphia, Pa.,

SENIOR RESIDENT DENTAL SURGEON, PHILADELPHIA GENERAL HOSPITAL.

VINCENT'S angina should be recognized by all dentists, from the fact that patients suffering from this disorder will visit the dentist first, believing that the trouble has its source in their teeth or gums, and usually around their third molars.

Definition. It is an acute infection of the mouth, the etiology of which is the action of *Bac. fusiformis* and a variety of spirillum (*Spirocheta denticola*).

SYMPTOMS.

The period of incubation is about six days; the onset is insidious. Although the throat may be little complained of, the granular enlargement will attract the

attention of the dentist, as it can be seen upon observation of the region around and below the angle of the jaw. The patient complains of headache and malaise, and the tongue is coated. The patient's temperature never exceeds 101° F., and is sometimes normal throughout the course of the disease.

CLINICAL FEATURES.

Upon observation of the mouth, the gums around the upper and lower second and third molars may show ulceration. There also may be found spots of ulceration upon the bucco-mucosal reflection, which may extend posteriorly toward the tonsil region.

Ulceration may become thickened, and when detached around the edges new membrane forms. This ulcerative tissue is necrotic tissue. In color it may be of the soft gray, yellowish gray, or greenish variety. There is a distinct fetid odor to the breath which is different from that of any other form of stomatitis.

In differentiating this from syphilitic chancre the following features are useful: (1) Angina ulceration is more tender to touch, (2) more superficial, (3) with granular enlargement in the region of the angle of the jaw, and (4) examination of the microscopic smear will determine the diagnosis.

I have treated several cases received in the Philadelphia General Hospital (Oral Surgical Department) and obtained excellent results.

The following record of a case will serve as an illustration:

Patient, a colored girl of twenty-eight, admitted January 4, 1917. At the Philadelphia General Hospital oral surgical clinic held January 6, 1917, by Dr. Carlton N. Russell, the case was diagnosed as Vincent's angina.

Physical examination showed ulcerations about the regions of the second and third molar teeth, also upon the buccomucosal reflection and posteriorly toward the tonsil region.

Symptoms. The patient complained that the teeth were all sore to touch; she could not eat, suffered with headache and malaise, and had difficulty in swallowing. There were present enlarged glands and swelling about the region of the angle of the jaw.

Two smears on glass slides were sent

to the laboratory and returned with a positive diagnosis of Vincent's angina. The patient's temperature ran normal.

Treatment. The patient was given a laxative, and ordered to use three times daily potassium permanganate (solution of 1:3000) with cotton upon applicators. Some of the ulcerative tissue was removed and the region swabbed with a 5 per cent. solution of hydrargyri nitras. The swollen region around the angle of the jaw was painted with 10 per cent. tincture of iodine. This treatment was continued, and the patient's condition cleared up in about eight days. This is only one of the many cases of Vincent's angina similarly treated with success.

Another antiseptic treatment used and from which I have obtained results is swabbing the parts with one of the following preparations: Copper sulfate 10 per cent., Lugol's iodine, phenol in glycerin 5 per cent., saturated solution of potassium permanganate.

In connection with the above I prescribe the use of a good germicidal mouthwash, such as potassium permanganate (solution 1:3000) or potassium chlorate.

Vincent's angina should be diagnosed and treated by all dentists, as it is a mouth condition which clearly falls within their scope of practice, especially as it is most likely to be presented first to the dental practitioner in its initial stages, when treatment should be promptly instituted to avert its extension and the loss of tissue by necrosis which results from its later and more extensive development.

1809 CHESTNUT ST.

Apothesine, the New Local Anesthetic: The Revised Technique of Pterygo-mandibular Injection.

By J. S. SHIELDS, D.D.S., Brooklyn, N. Y.

AT this time, when American chemical ingenuity is so sorely needed and its products are so carefully watched, I cannot refrain from reporting my observations of and conclusions from a series of over 700 oral operations under local anesthesia induced by the new American synthetic local anesthetic—apotesine. These operations were performed at the Vanderbilt Clinic of the College of Physicians and Surgeons, New York, during a period of two months, between November 9, 1917, and January 11, 1918. In a series of 380 cases, 703 extractions were done, 151 of which were anesthetized by infiltration by subperiosteal and peridental injections, the remaining 229 by conduction through perineural injection of the pterygo-mandibular nerve. There were also sixteen minor operations, including root amputations, removal of small cysts, fibrous tumors, and plastic operation to close the palate. In another series of cases there were twenty-five double pterygo-mandibular injections. The anesthetic solution in each case consisted of apotesine 2 per cent. and adrenalin 1:50,000. The solutions were prepared by dissolving one tablet of apotesine combined with adrenalin for every 2 cc. of Ringer solution used, and boiling the solution over an alcohol flame for sterilization. Profound anesthesia was induced in one minute when infiltration was the method employed, and it is even more noteworthy that when conduction was resorted to, the average time in which complete anesthesia resulted was eight minutes. Untoward symptoms such as pallor, syncope, or palpitation

were conspicuously absent during the whole series. The anesthesia in each case was absolute, and in those cases that were observed an hour and a half after injection (impacted third molars) sensation had not yet returned. My observations with regard to the toxicity of apotesine and its non-interference with primary wound healing coincide entirely with those of Prof. Arthur Dean Bevan, president-elect of the American Medical Association, which he records in the *Chicago Surgical Clinics* of February 1917, in the following language: "I have recently used apotesine in twenty-five operations, including removal of inguinal glands, resection of rib, and drainage of lung abscess, circumcision, inguinal and femoral hernia, carcinoma of the face, synovial cyst on the back of the wrist, ligation of thyroid vessels, gastro-enterostomy, resection of rib, and draining subphrenic abscess, a very extensive thyroidectomy, removal of bullet from the thigh, removal of infected cyst of the neck, and removal of tumor of the breast. We have used as large an amount as five and one-half ounces of a half of one per cent. solution. We have not noticed any toxic effects of any kind, and no interference with primary wound healing." Owing to apotesine's entire freedom from habit-forming properties, its purchase and sale is not restricted by any of the provisions of the Harrison narcotic law.

CHEMICAL COMPOSITION OF APOTESINE.

To discuss technically the chemistry of apotesine is beyond the scope of this

paper. I shall attempt, however, to give the reader a conception of the structure of this substance which will be adequate for his purpose. Ever since the discovery of cocain by Niemann in 1859 and the subsequent demonstration of its anesthetic properties in 1884 by Koller, it has been the goal of chemists to produce synthetically a substance having the anesthetic power of cocain without its dangerous, poisonous character. In 1865 Lossin showed that cocain when split into its component parts consisted of benzoic acid, methyl alcohol, and ecgonin, a complex substance related to atropin. Future attempts at synthesis were based upon this analysis, and one principle which has since been shown to be an essential in the building of the molecule of a local anesthetic has been adhered to; that principle is the formation of an ester by combining an acid with an alcohol. Considered from this standpoint, cocain is the methyl-benzoyl ester of ecgonin. In 1897 Einhorn and Heinz made an important step forward, and produced orthoform, which is chemically the methyl ester of para-amino-oxybenzoic acid. By slight changes in the molecular structure of orthoform they subsequently evolved nirvanin, holocain, and acoin. In 1901 Ritser made another important advance in producing anesthetics, the ethyl ester of para-amino-benzoic acid. Fourneau in 1904 and Impens in 1905 produced respectively stovain and alypin. Up to this time no synthetic local anesthetic answered all the requirements as promulgated by Braun, the father of local anesthesia. These requirements in effect are that the substitute should be relatively non-toxic, that it should not be inferior to cocain in anesthesia-producing power, that it should be non-irritating even to most delicate tissues, that it must combine with adrenalin without deterioration of itself or the adrenalin, and that it must be soluble in water and boilable. This ideal was approached in 1905 by Einhorn when he made the diethyl-amino-ethanol ester of para-amino-benzoic acid, or what is known as novocain. In this newest development, apothesine,

it can safely be said that the goal has been attained, and we now have in apothesine the perfect local anesthetic. It differs from novocain in that instead of being essentially an ethyl ester of benzoic acid, it is a propyl ester of cinnamic acid. Thus, propyl alcohol is used instead of ethyl alcohol, and cinnamic acid in place of benzoic acid. In my hands it has fully answered all the requirements of Braun.

TECHNIQUE OF INJECTION.

The technique of inducing conduction anesthesia by injection of the pterygo-mandibular nerve can easily be acquired by practice. The operator must have a clear idea of the anatomy of the ramus of the jaw and the relations of the nerves and vessels on its inner aspect. To determine the site of puncture the index finger is placed on the external oblique line of the ramus and pushed posteriorly until the retromolar triangle is felt. (Fig. 1.) This triangle is formed by the sides of the internal and external oblique lines. If the finger be now raised until it is about one centimeter above the occlusal surfaces of the molars, the anterior border of the ramus is palpated. In this procedure of finding the site for puncture, the finger should be kept in constant contact with the tissues, and is to be swabbed, together with the surrounding mucous membrane, with tincture of iodine. The point of the needle is now placed upon the finger-nail of the guiding finger, and is carefully slid toward the mucous membrane. The needle must puncture the mucous membrane at a point high enough to avoid the internal pterygoid muscle. The needle is advanced until the bone is encountered, then slightly withdrawn to the submucous tissue, and borne over the internal oblique line to the inner aspect of the ramus. The hand and syringe are now moved mesially and the needle is again pushed forward, this time slightly outward, to conform with the direction of the inner surface of the ramus. When the needle has passed over the lingula it is in the pterygo-mandibular space, where the anesthetic solution

should be injected. (Fig. 2.) *The needle must be in contact with the ramus throughout its course from the internal oblique line to the pterygo-mandibular space.* I mount my syringe with a 1½-inch needle on a short hub. Using a needle of this length with a short hub allows sufficient needle space between the mucous membrane and the hub, thus minimizing the danger of breaking the needle

appear. When the preliminary injection is made in the region of the lingual nerve, the side of the tongue also presents these symptoms. Apotheresine acts so quickly that usually in five minutes the whole region supplied by the pterygo-mandibular nerve—the mandible, gums, pulps, etc.—is completely anesthetized.

I have not taken up the technique for the infiltration injections or the

FIG. 1.

Showing needle in the retromolar triangle.

FIG. 2.

Showing needle in the pterygo-mandibular space.

through the necessary bending. The needle should preferably be steel. This is important, because the necessary change of direction can more easily be made with a rigid needle. A platinum-iridium needle is more yielding, and therefore the surface of the ramus is adhered to with difficulty. A few drops of the apotheresine solution should be injected at the point of insertion to anesthetize the lingual nerve. When the pterygo-mandibular space is reached, the remainder of the contents of the syringe is injected, and during injection a constant backward and forward motion is maintained. This is done to obviate the possibility of injecting the entire quantity into a bloodvessel. The anesthetic solution quickly permeates the trunk of the pterygo-mandibular nerve, and the characteristic symptoms of tingling and numbness of the cheek and lip

other conduction injections, because my methods do not differ from those of most operators.

CONCLUSIONS.

(1) Apotheresine is equal to cocain in anesthesia-producing power.

(2) It does not deteriorate when combined with adrenalin, nor does it impair the efficacy of the adrenalin.

(3) It does not irritate even delicate tissues.

(4) It produces anesthesia by infiltration in one minute, and by conduction in from five to ten minutes.

(5) It is boilable without deterioration, and is freely soluble in water.

(6) It is less toxic than any other known local anesthetic.

585 JEFFERSON AVE.

Brief Review of Current Dental Literature.*

By L. P. ANTHONY, D.D.S., Philadelphia, Pa.

(Read before the Academy of Stomatology of Philadelphia, March 6, 1918.)

YOUR committee has asked me to present a review of the current periodical literature on the various aspects of the practice of dentistry, and in making this request the committee impressed on me the necessity for brevity more than any other feature. There was some question in my mind as to whether I should attempt to review the literature or simply present a summary of it in more or less bibliographical style, and because of this time limitation and because the field to be covered is so large, I chose the latter course, and shall attempt simply to give you a bird's-eye view of what has been published during the past few months.

I have therefore classified the contributions according to the various specialties rather than according to periodicals, and give under each classification the title of the article, the author, and the journal in which it appears, commenting briefly on those which may be considered worthy of special note:

OPERATIVE DENTISTRY.

"The Principles of Black's Cavity Preparation." R. R. BYRNES, *DENTAL COSMOS*, January 1918. A clear and concise exposition of the principles of cavity preparation as taught by the late Dr. G. V. Black.

"The Manipulation of Amalgam." THOMAS H. HINMAN, *Dental Items of Interest*, January 1918. Dr. Hinman

stands high in the field of operative dentistry, and his paper will doubtless prove of interest and value to all operative dentists.

"Dental Treatment in the English Army." Captain W. L. CROCKER, *DENTAL COSMOS*, February 1918. A very interesting account of the author's experience in practicing general dentistry in the English army.

"Where Will We Place Gold Foil Among Our Filling Materials?" J. M. PRIME, *Minneapolis District Dental Journal*, November 1917. In this day of gold inlays, amalgam fillings, etc., the profession has been much inclined to neglect the gold foil filling, but Dr. Prime comes to the defense of the gold foil filling in an admirable manner, claiming that the gold foil filling is by no means a lost art, and that it will soon come to its own again.

PROSTHESIS.

"Impressions for Full Dentures." GEORGE H. WILSON, *Pacific Dental Gazette*, January 1918. The particular feature worthy of note in Dr. Wilson's article is that in spite of the popularity of modeling compound for taking impressions for full dentures, he is still firm in his belief that plaster is the best material for this purpose.

Dr. Wilson has also issued a revised edition of his well-known book on Prosthetics—"A Manual of Dental Prosthet-

* This review, covering the literature for December 1917 and January and February 1918, was prepared at the request of the Academy. It is the intention of the Academy to have similar reports prepared, say every two months, until the dental literature for the year is covered.

ics," by GEORGE H. WILSON, Philadelphia, Lea & Febiger, 1917.

"Methods of Taking Modeling Compound Impressions with the Mouth Closed and Under Normal Biting Strain." J. H. DREXLER, DENTAL COSMOS, February 1918. A very clear description of the Greene method of impression taking.

"Type vs. Temperament." NORMAN S. ESSIG, DENTAL COSMOS, September, November, and December 1917, and February 1918. A series of articles constituting a valuable contribution to the subject of prosthetic dentistry, in that it presents to the profession a definite system for the selection of teeth in making artificial dentures. Dr. Essig's system is based on the classification of three basal types of dentures, and by his method one is enabled to reproduce any type of teeth from combinations and variations of the basal types.

"Notes on Prosthetics." D. M. SHAW, *Dental Record*, February 1918. A continuation of an excellent series of articles covering the field of prosthetic dentistry.

"Practical Suggestions in Plate Work." F. J. SMITH, *Dental Review*, February 1918. A description of the technique of impression taking according to the Hall method.

ORAL SURGERY.

"Surgery and Diseases of the Mouth and Jaws." Major V. P. BLAIR, published by C. V. Mosby Co., St. Louis, and "Injuries of the Face and Jaw," by MARTINIER and LEMERLE, two noted French surgeons, published by Wm. Wood & Co., New York. Two text-books on oral surgery in which the more recent methods of treating war injuries will be found.

"The Histology and Pathology of Alveolar Abscesses and Diseased Root-ends." KURT H. THOMA, DENTAL COSMOS, January 1918.

"Impacted Lower Third Molars." C. EDMUND KELLS, DENTAL COSMOS, February 1918. The special feature of Kells' paper is the presentation of a method for cutting away a portion of the crown of a tooth impacted in a horizontal

position, and then with specially designed forceps drawing the tooth forward into the space made by cutting away the crown and removing it with an elevator or the forceps. The author claims almost universal success with this system where teeth are impacted in a horizontal position, and says that there is seldom any necessity for after-treatment of the wound.

"Three Rare Cases of Replantation of the Teeth." ANGELO CHIAVARO, *Annali di Odontologia*, December 1917. Dr. Chiavaro advocates the same method of treatment, i.e. extraction and replantation, as that proposed by Marshall in his paper.

"Apical Infection and Its Treatment," JOHN S. MARSHALL, *Journal of the National Dental Association*, October 1917—both writers claiming abundant success in following this rather heroic method of treatment of chronic apical abscesses in selected cases.

"The Treatment of Root-canals with Putrescent Pulp." CARL J. GROVE, *Journal of the National Dental Association*, January 1918. A further elaboration of the author's ideas of strict asepsis and thorough cleanliness in root-canal operation.

Two other valuable contributions to this subject are—

"The Surgical Technique of Root Resection in Granuloma Cases." CARL D. LUCAS, *Dental Summary*, January 1918; "A Method of Filling Root-canals." I. L. FURNESS, *Dental Summary*, January 1918.

"Fractures and Dislocations of the Jaws." CHALMERS J. LYONS, *Dental Summary*, January and February 1918. A series of articles by a writer of considerable prominence on the treatment of fractures from various causes, which being written in more or less text-book style, will doubtless prove of considerable value to the student as well as to the practitioner of oral surgery.

As related particularly to war surgery, the following articles will be found valuable and instructive:

"Two Cases Illustrating Plastic and

Dental Operations." H. D. GILLIES, *Lancet*, December 1917.

"A Few Notes on the Treatment of Gunshot Wounds of the Mandible and Maxilla." W. KELSEY FRY, *Lancet*, December 1917.

"Healing of Lower Jaw-bone Defects in War Cripples." J. F. ESSER, *American Journal of Surgery*, December 1917.

"Cartilage Transplantation in Extensive Wounds of the Lower Jaw." M. MORESTIN, *Presse Médicale*, August 1917.

PATHOLOGY AND BACTERIOLOGY.

"The Present Status of Dental Bacteriology." K. F. MEYER, *Journal of the National Dental Association*, September 1917. With regard to the relationship of oral sepsis and systemic disturbances, Meyer says that the evidence is not convincing as to the exact relation of cause and effect, and adds that one should suspect the presence of pre-existing disease as an underlying factor in oral sepsis before resorting to mutilating dental operations.

"The Influence of General Health on Oral Tissue." LEROY M. S. MINER, *DENTAL COSMOS*, March 1918, presents practically the same phase of the question as Meyer, claiming that so far as the relationship of mouth and systemic conditions is concerned his experience has proved that mouth conditions are as often the result of systemic conditions as they are the cause, and in proof of his contention he presents numerous cases from practice in which mouth conditions have quickly cleared up after the correction of certain systemic disturbances.

"The Pathogenesis of Focal Infection." E. C. ROSENOW, *Journal of the National Dental Association*, February 1918. A further elaboration of the author's studies on the localization of bacteria. Rosenow presents numerous laboratory experiments which tend to further substantiate his original findings.

"Some Mucous Membrane Affections of the Mouth." M. L. HEIDINGSFELD, *Dental Summary*, February 1918. In this paper the author shows the desirability of co-operation between the dermatol-

ogist and the dentist, and describes a number of disease conditions of the skin with which dentists should be familiar.

"Pyorrhea." F. H. SKINNER, *Dental Summary*, February 1918. A detailed description of the writer's technique of instrumentation in connection with the Dunlop vapor treatment for pyorrhea.

STUDIES OF SALIVA AND THE INTERNAL SECRETIONS.

"The Relationship of Oral Secretions to Dental Caries." HERMANN PRINZ, *DENTAL COSMOS*, February and March 1918. Two of a series of articles by Dr. Prinz presenting a new theory with regard to the etiology of dental caries, his belief being that susceptibility and immunity to dental caries bear a definite relation to the salivary enzyme content, e.g. that persons with abnormal saliva are more susceptible to caries than those whose saliva is normal. The author presents a series of valuable scientific studies in support of his belief.

"An Experimental and Clinical Study of the Isolated Thyroid Hormone." NELSON W. JANNEY, *DENTAL COSMOS*, February 1918. An exceedingly interesting paper in that it presents a new theory as to the functions and correlations of the internal secretions.

ANESTHESIA.

"Nerve-Blocking." A. E. SMITH, *Minneapolis District Dental Journal*, November 1917. A paper along similar lines to the classic on this subject published by Dr. Hermann Prinz some years ago: "Modern Methods of Local Anesthesia," *Dental Review*, March 1913.

"Selection of Anesthetic for Oral Operations and the Roentgen Ray as an Aid in Diagnosis." KURT H. THOMA, *DENTAL COSMOS*, March 1918. A paper which should be helpful to the oral surgeon in the selection of the proper anesthetic for a given operation.

"The Comparative Efficiency of Local Anesthetics." TORALD SOLLMAN, *Journal of the American Medical Association*, January 1918.

"Why Chloroform is a More Powerful and Dangerous Anesthetic Than Ether."

W. E. BURGE, *Science*, December 1917. A study of the relative safety of chloroform and ether.

"Administration of Nitrous Oxid for Dental Operations." J. E. H. ATKEISEN, *Dental Review*, February 1918.

"Indications and Practical Application of Local Anesthesia in Dentistry." P. T. PUTERBAUGH, *Dental Review*, February 1918.

ORTHODONTIA.

"Observations on the Form of the Dental Arch of the Orang." MILO HELLMAN, *International Journal of Orthodontia*, February 1918. A scientific study in comparative anatomy from the orthodontic standpoint.

"Photo-Surveys of the Human Dentures." RUDOLPH L. HANAU, *International Journal of Orthodontia*, February 1918.

"Movement of Teeth Predetermined by Engineering Instruments." F. L. STANTON, *DENTAL COSMOS*, January 1918.

"Orthodontic Treatment of Advanced Cases, and Patients Coming from a Distance." J. A. C. HOGGAN, *DENTAL COSMOS*, January 1918.

BRIDGE WORK.

"A Simple Form of Removable Bridge Work with Cast Clasps." NORMAN B.

NESBETT, *DENTAL COSMOS*, March 1918. A very timely paper in view of the discussion now going on with regard to advantages and disadvantages of removable and fixed bridges.

"Crown and Bridge Work from the Standpoint of the Periodontist." GILLETTE HAYDEN, *Journal of the National Dental Association*, February 1918. Also interesting as bearing on the question of removable and fixed bridge work.

"Mobile Bridges." L. GORMSEN, *Dental Items of Interest*, February 1918. An exposition of extensive bridge work, employing the arch bar as advocated originally by L. C. Bryan.

ORAL HYGIENE.

(a) "Film Showing the Technique of Dental Prophylaxis for the Dental Hygienist." (b) "An Educational and Preventive Dental Clinic in Public Schools of Bridgeport." (c) "Mouth Hygiene for the United States Soldiers Stationed at Bridgeport, Conn." A. C. FONES, *Journal of the National Dental Association*, February 1918. This series of articles deals more particularly with the question of oral hygiene from the standpoint of the education of the dental hygienist and the benefits of oral hygiene to the public generally.

211 SOUTH TWELFTH ST.

The Bearing of Physical Anthropology on the Problems of Orthodontia.

By L. R. SULLIVAN, M.A., New York, N. Y.,

DEPARTMENT OF ANTHROPOLOGY, AMERICAN MUSEUM OF NATURAL HISTORY, NEW YORK, N. Y.

(Read at the meeting of the Eastern Association of Graduates of the Angle School of Orthodontia, January 26, 1918, held at the American Museum of Natural History, New York, N. Y.)

MY purpose in presenting this paper is to show that physical anthropology has a very definite bearing on the problems of orthodontia, and that the two sciences can be mutually beneficial. In view of the fact that there is a tendency to confuse the results of morphological and psychological research in anthropology, I think it is permissible to define, very briefly, the scope and aims of physical anthropology.

Physical anthropology is that phase of biology which deals with man; it analyzes that thing which we call race. This process includes a study of those characters which go to make up external body form, such as hair, skin, eyes, ears, bodily proportions and muscular development, as well as a more minute study of the internal anatomy. It also includes a study of the phylogeny, embryology, pathology, and physiology of man. Physiology, in its turn, includes psychology, which, however, is more adequately treated in other branches of anthropology.

The purpose of physical anthropology is to gain a more definite knowledge of the relationships of the several races of living man with one another, with the various types of prehistoric man, and with other members of the order of primates. In brief, it is to reconstruct the morphological history of mankind.

It will be readily seen that our problem is complicated, and necessitates highly specialized workmanship in every phase. The majority of physical anthro-

pologists must devote themselves to some of the broader aspects of the subject, and depend on the specialist for more detailed knowledge within a special field. While I feel that physical anthropologists can do much for orthodontia, I am certain that orthodontists can do much more for physical anthropology, and at the same time perform a real service for their own profession.

To be sure, our points of view are different. The practicing orthodontist is interested primarily in the individual. Anthropology is concerned with the individual only in so far as he forms a part of a tribe, racial type, or race. But even in orthodontia it would seem more practicable, within certain limits, to apply the characters of a racial type to the individual rather than apply the characters of an individual to a race as a whole.

Whether he recognizes them or not, the orthodontist, dentist, or physician is confronted by some of the same problems as the anthropologist. Like the comparative anatomist, paleontologist, and systematist, we are dealing with a biological problem. Unlike them, we are dealing with very small, yet just as distinct and as constant differences; we are confronted by details with which they have not, as yet, concerned themselves. These racial differences must be recognized just as in the zoölogical world proper we recognize specific and generic differences. Our problem is complicated further by the constant intermixture of racial types, and

our inability to comprehend fully the mechanism of heredity.

From our colleagues, mentioned above, we acquire the tendency to interpret changes or variability in terms of cause and effect. The principle is an excellent one, and a very convenient way in which to interpret nature. Yet I think the tendency of some practitioners has been to exaggerate the influence of mechanical forces on the individual; to some the body has become a mere ball of clay, easily molded in any direction. We must not forget that systematists, in explaining phylogeny on the basis of cause and effect or adaptation, speak in very general terms, and imply a great number of causes besides those mentioned, and also presuppose a great period of time in which the changes have come about.

To say that in the course of time the excessive heat and rays of the sun have caused the hair of the negro to become frizzly and his skin to become black is one thing, but to expect the sun to have a similar effect on an individual or even on a large number of generations within our own brief historical background is entirely different. The first statement could probably never be proved or disproved to one inclined to reject or accept it. Yet, to the anthropologist, the negro is something more than a dark skin and frizzly hair; he is a biological problem. Closely correlated with these characters of skin and hair, we find a wide, short, flattened nose, short ears, thick lips, long limbs, large teeth, projecting face, a tendency to longheadedness, and a very definite form of skull and skeleton. In view of this great number of closely associated characters it seems hardly fair to segregate a single character and explain it by a single causal factor.

Again, the causes which we assign are necessarily limited by our experience and background. This accounts for the fact that we may have a score of different causes applied by as many workers explaining the same variation—and one is as likely to be correct as the other. It would be more probably correct to say that all these and many other factors enter into the causal complex. A short

time ago it was noised about that the narrow-toed English shoes were rapidly causing the little toe of man to become vestigial. Sometime later, when the same dwindling little toe was found among the earliest Egyptian mummies and among tribes never encumbered with footgear, we felt relieved, and the English shoes were exonerated. This would seem to show that the most obvious reason is not always the real cause. Only last week I read a statement to the effect that the Chinese expended so much of their energy in growing a queue that they were unable to grow a beard. Now that the practice of growing a queue has been abolished, it has been predicted that the Chinese would speedily recover and develop beards. A glance at some other Mongolian and Negroid types discourages us from taking such a statement seriously.

INFLUENCE OF ENVIRONMENT ON THE DEVELOPMENT OF TYPES.

It is not my purpose to discourage the search for environmental influences. In fact, I believe that environment is a very important factor in evolution, especially when extended, as has been done by W. K. Gregory⁽²⁾, to mean internal environment as well as external environment. But these generalizations must be considerably modified before they are applicable to the individual. The extent of these influences is determined by the plasticity of the individual, which is regulated by growth. A fuller knowledge of the process of growth will help us to keep our theories of cause and effect, as applied to the individual, within the bounds of reason.

As an example of the malleability of the human body in infancy we may examine some of the types of head form produced by the American Indians by means of bandages and mechanical devices. In fact, the head, is sometimes unintentionally deformed by the use of a hard cradle board.

The muscles undoubtedly leave their markings on the skeletal system; the conformation of joints is also influ-

enced by function. This skull of an Eskimo [exhibiting] illustrates both of these points. This individual had a misplaced premolar on the right side. For some reason or other it was evidently inconvenient for him to masticate on that side. The teeth show no perceptible traces of wear. Consequently he has shown a preference to use his left incisors and canines almost exclusively. In order to do this it was necessary to use the right internal pterygoid muscle more strenuously than the left. As a result we have a very much heavier condyle on the right side, and a much more sloping articular eminence bounding the right glenoid fossa. The markings of the temporal muscles also show well in this skull, being nearer to the sagittal suture here than in any skull yet reported on.

RACE THE CONTROLLING FACTOR IN THE DEVELOPMENT OF TYPES.

We come now to the other controlling factor which we call race. Among mankind we recognize at least three primary races of living man, Mongoloid, Negroid, and Caucasian, with a strong probability of the Australian constituting a fourth. Each of these primary races may be further subdivided into four or five fairly distinct racial types. Each race, and in turn each racial type, possesses a peculiar combination of characters by means of which we may recognize it from any other race or racial type. Certain individual characters may be common to two races, but not in the same combination. Some racial types present such a blending of characters that it is difficult to decide to which of two primary races they may belong. The Australian is a good example of this.

Certain characters seem to be fairly constantly confined to a single race—the woolly hair and short broad nose to the Negroid types, the peculiar fold of the eye and the broad face to the Mongoloid types, the light skin and well-developed beard and abundant body hair to the Caucasian. Other characters apparently jump racial boundaries and appear in more than one race. Stature, barring the

extremes, is more distinctive of racial types than of race. The tendency to long- and short-headedness appears in all races, yet is very constant for racial types. The high-arched nose of the Semitic peoples is duplicated among North American Indians.

I shall not go into detail on the matter of race, but shall only attempt to draw a few examples a little nearer your special field. I have not made a detailed study of teeth, and can speak only in very general terms. We recognize racial differences in the size of teeth. It has also been shown that certain anomalies of the teeth occur more frequently in one race than in another. But after all I have said about the persistence of racial traits we should expect to find some of the same distinct racial differences in teeth that we find in other parts of the body. I know of only one well-established case. Dr. Hrdlicka has shown that the American Indian and Eskimo show very peculiar, infolded, shovel-shaped upper incisor teeth. This character, though less accentuated, occurs in the teeth of other Mongoloid types.

I have followed with considerable interest the persistent appearance of papers attempting to correlate tooth form with certain mental types, and the equally persistent attempts of other workers to show that no such correlation exists. If we accept these types as psychological types the thesis becomes absurd, but if we call them morphological types I believe the subject deserves further consideration. The attempt to correlate tooth form with biological types should not be abandoned until it has been demonstrated beyond any doubt that such a correlation does not exist.

RELATION OF THE DIFFERENT PARTS OF THE SKULL.

On two* occasions you have had presented to you one of the principles of comparative anatomy, namely, the principle of dolichocephaly and brachyceph-

*No attempt is made to reconstruct the extensive literature bearing on this subject.

ally extended to the form of the face and alveolar arch. It was first definitely formulated by Prof. H. F. Osborn⁽³⁾. In 1905 Dr. E. H. Angle⁽¹⁾ applied similar concepts to man. In 1910 Dr. Raymond C. Osburn⁽⁴⁾ extended Prof. H. F. Osborn's principle to man. These papers have shown beyond any doubt that there are distinct differences in the conformation of the dental arch among normal individuals.

The principle of dolichocephaly (long-headedness) and brachycephaly (short-headedness) assumes that all parts of the skull are in harmony. If the brain-case is long and narrow, the face, including the alveolar arch, will be correspondingly

several parts of the skull the principle presented great possibilities in our analysis of race. Like most proposals which reduce biological phenomena to simple compensating interactions, this principle seems to be far from universal in its application. It is very probable that the scientists mentioned above would not claim so much for the principle at the present time.

I am not prepared to speak in any detail on the subject. I have simply looked into the matter in its broader aspects, and have confined my inquiry to the main proportions of the brain-case and face, including the alveolar arch. The accompanying Table I gives us an oppor-

TABLE I.—COMPARISON OF LENGTH-BREADTH INDICES OF BRAIN-CASE AND ALVEOLAR ARCH.

| Race. | Cranial index. | Maxillo-alveolar index. | Observer. |
|------------------------------|----------------|-------------------------|------------|
| 1. Australian | 71 | 109 | Turner. |
| 2. Tamil | 71 | 113 | Sarasin. |
| 3. Vedda | 72 | 117 | " |
| 4. Kafir | 72 | 107 | Shrubsall. |
| 5. Eskimo | 73 | 124 | Oetteking. |
| 6. Singhalese | 73 | 108 | Sarasin. |
| 7. Indian, New York | 74 | 116 | Hrdlieka. |
| 8. Tasmanian | 75 | 115 | Berry. |
| 9. Old Egyptian | 75 | 118 | Oetteking. |
| 10. Maori | 76 | 123 | Bauer. |
| 11. Indian, Virginia | 76 | 115 | Hrdlieka. |
| 12. Scotch | 77 | 113 | Turner. |
| 13. Swede | 77 | 113 | Duben. |
| 14. Indian, California | 77 | 115 | Hrdlieka. |
| 15. North Chinese | 78 | 124 | Reicher. |
| 16. Kalmyk | 81 | 125 | " |
| 17. Buriat | 84 | 125 | " |
| 18. Tirolese | 85 | 118 | Wacker. |
| 19. Tourgout | 85 | 126 | Reicher. |
| 20. Telenget | 86 | 124 | " |

long and narrow. The reverse would be true in a skull having a short, wide brain-case. It also asserts that the component parts, such as the teeth, zygomatic arch, etc., will conform to type. The whole principle is so simple, logical, and plausible that I became interested in it. If such a relationship existed between the

tunity to compare the main proportions of the brain-case with the main proportions of the alveolar arch. Both of these indices express the proportion of breadth to length in terms of per cent. That defining the brain-case is called the cranial index, and the one expressing the proportions of the alveolar arch is called

the maxillo-alveolar index. In either case a small index denotes a relatively long, narrow structure, and a high index the reverse.

The cases selected represent fairly well the ranges of the two indices in man. Inspection of the table shows a loose relationship between the two indices. The long-headed Australian and Kaffir have an elongated alveolar arch; at the other end of the scale the Mongoloid Buriat, Tourgout, and Telenget have a wide alveolar arch. Yet there are numerous discrepancies. The North Chinese, with a relatively longer head, have a very short,

But just as I said that it is impracticable for the dentist, orthodontist, or physician to apply the broader principles of comparative anatomy to the individual, it is equally impracticable to apply the generalizations of the anthropologist.

CORRELATION OF MEASUREMENTS OF THE DIFFERENT PARTS OF THE SKULL.

Coming down to the individual, I have attempted to determine which of these measurements were more closely related, and to what extent any two of the dimensions varied together. This is called

TABLE II.—COMPARISON OF ABSOLUTE MEASUREMENTS OF PALATE WITH ABSOLUTE MEASUREMENTS OF BRAIN-CASE AND FACE.

(Palate measurements expressed in percentage of the diameters of brain-case and face.)

| Race. | Greatest length of palate to greatest length of brain-case. | Greatest width of palate to greatest width of brain-case. | Greatest width of palate to greatest width of face. |
|------------------|-------------------------------------------------------------|-----------------------------------------------------------|-----------------------------------------------------|
| Eskimo | 29.5 per cent. | 45.0 per cent. | 44.0 per cent. |
| Telenget | 30.5 " " | 42.0 " " | 46.0 " " |
| Singhalese | 31.0 " " | 46.0 " " | 48.0 " " |
| Kaffir | 30.0 " " | 46.0 " " | 47.0 " " |
| Tamil | 29.5 " " | 48.0 " " | 50.0 " " |
| Vedda | 28.0 " " | 46.0 " " | 47.0 " " |
| Tasmanian | 30.0 " " | 47.5 " " | 50.0 " " |

wide alveolar arch; the Eskimo, with an elongated head, have a short, wide arch. The proportions of the arch among American Indians and among the Mongols proper seem to remain fairly constant, regardless of differences in head length. While there are cases in which the brain-case and alveolar arch are in harmony, it would seem that the correlation is too loose to be of any service to a practitioner. To my mind the racial relations are more significant than the relationships of brain-case and alveolar arch. Race implies more than dolichocephaly and brachycephaly.

In Table II, I have compiled the relationship of the absolute measurements of the alveolar arch and the brain-case and face. These show a fairly constant relationship throughout.

correlation. The basis of comparison is unity, or 1. Unity denotes a perfect correlation. For example, if we should find that the width of the palate always varied with the width of the brain-case, and at the same proportionate rate, the coefficient of correlation would be 1, *i.e.* we should have a perfect correlation. Perfect correlations are rare. Orthodontists and dentists must apply some such method in order to obtain accurate working principles. Rather than be satisfied with the generalization that a long palate always accompanies a long brain-case, we can determine mathematically with some degree of certainty in how far such a statement is true.

In my investigation I have confined myself to one sex. The differences between male and female are very large in

some racial types. The observations on the Eskimo were made on a series in the American Museum of Natural History, and are from Alaska. The measurements on which I based my calculations for the Telenget and Kaffir were taken from Reicher⁽⁶⁾ and Shrubsall⁽⁷⁾ respectively. I fully realize that orthodontists rarely come in contact with individuals of these racial types. The selection was necessitated in order to obtain a homogeneous series of any considerable size.

The measurements used were—

(1) *Cranial index*—Greatest breadth of brain-case. Greatest length of brain-case.

(2) *Maxillo-alveolar index* — External breadth of alveolar arch; external length of alveolar arch.

(3) *Greatest length of brain-case*—Glabella to Opisthocranium.

(4) *Greatest breadth of brain-case*—Euryon to Euryon.

(5) *Base of brain-case*—Basion to Nasion.

(6) *Breadth of face*—Maximum Bizygomatic.

(7) *Length of face*—Basion to Prosthion.

(8) *Greatest breadth of palate*—External.

(9) *Greatest length of palate*—External.

TABLE III.—CORRELATIONS.

INDICES.

I. *Cranial Length-breadth Index with Maxillo-alveolar Index.* (Proportions of brain-case with proportions of alveolar arch.)

| | | |
|------------------|----------------------------------|-----------|
| Eskimo....[36M] | Coefficient of correlation | .18 ± .11 |
| Telenget...[40M] | “ “ “ | .13 ± .10 |
| Kaffir.....[36M] | “ “ “ | .11 ± .10 |

MEASUREMENTS OF LENGTH.

II. *Greatest Length of Brain-case and External Palatal Length.*

| | | |
|------------------|----------------------------------|-----------|
| Eskimo....[47M] | Coefficient of correlation | .70 ± .04 |
| Telenget...[43M] | “ “ “ | .19 ± .10 |
| Kaffir.....[38M] | “ “ “ | .26 ± .10 |

III. *Base of Brain-case and External Palatal Length.*

| | | |
|------------------|----------------------------------|-----------|
| Eskimo....[47M] | Coefficient of correlation | .52 ± .07 |
| Telenget...[43M] | “ “ “ | .39 ± .09 |
| Kaffir.....[38M] | “ “ “ | .35 ± .09 |

IV. *Length of Face and Length of Palate.*

| | | |
|------------------|----------------------------------|-----------|
| Eskimo....[47M] | Coefficient of correlation | .90 ± .02 |
| Telenget...[43M] | “ “ “ | .63 ± .07 |
| Kaffir.....[38M] | “ “ “ | .76 ± .05 |

V. *Length of Brain-case and Base of Brain-case.*

| | | |
|------------------|----------------------------------|-----------|
| Eskimo....[47M] | Coefficient of correlation | .62 ± .06 |
| Telenget...[43M] | “ “ “ | .58 ± .07 |
| Kaffir.....[38M] | “ “ “ | .68 ± .06 |

MEASUREMENTS OF BREADTH.

VI. *Greatest Width of Brain-case and Greatest Width of Palate.*

| | | |
|------------------|----------------------------------|-----------|
| Eskimo....[47M] | Coefficient of correlation | .07 ± .10 |
| Telenget...[43M] | “ “ “ | .36 ± .09 |
| Kaffir.....[36M] | “ “ “ | .00 |

VII. *Width of Face (bizygomatic) and Greatest Width of Palate.*

| | | |
|------------------|----------------------------------|-----------|
| Eskimo....[47M] | Coefficient of correlation | .40 ± .08 |
| Telenget...[43M] | “ “ “ | .31 ± .10 |
| Kaffir.....[36M] | “ “ “ | .53 ± .08 |

VIII. *Greatest Width of Brain-case and Greatest Width of Face (bizygomatic).*

| | | |
|------------------|----------------------------------|-----------|
| Eskimo....[47M] | Coefficient of correlation | .45 ± .08 |
| Telenget...[43M] | “ “ “ | .41 ± .02 |
| Kaffir.....[36M] | “ “ “ | .15 ± .11 |

The number of cases is very small and the error correspondingly large, yet these figures give an approximation to the relationship.

We get no certain correlation for the indices. Length of brain-case and length of palate show a fair degree of correlation among the Eskimo only. There seems to be a fairly constant relationship between the base of the brain-case and length of palate. A much higher degree of correlation is shown between the length (not height) of the face and length of the palate. But this is a spurious correlation, inasmuch as the length of the face includes the length of the palate. An elongated palate adds to the length of the face.

In the measurements of breadth we find no certain correlation between width of brain-case and width of palate except for the Telenget. The most constant relationship is between width of the face and width of palate. I feel more certain about this correlation, inasmuch as it agrees rather closely with the results of Wissler and Channing⁽⁸⁾ in a more detailed study of the palate. The width of the face and width of brain-case show a positive correlation for the Eskimo and Telenget. It would seem that in these instances the head and face vary together; yet the proportions are reversed. The transverse diameter of the head exceeds the transverse diameter of the face in the Telenget, while the reverse is true for the Eskimo.

DEVELOPMENT OF THE INDIVIDUAL NOT CONTROLLED BY THE BIOLOGIC FACTOR WHICH DETERMINES TYPE.

These correlations bring out a very important point in biological research. The factor originally giving rise to and determining a biological type does not wholly determine the development of the individual. Certain developmental and environmental factors may enter into the growth of the individual, and in some cases cause him to depart in certain characters from the mean of the biological type of which he is a member. But it is also apparent that these individual variations are limited by the factors

which determine biological types. Thus a generalization which applies to a racial type does not necessarily apply to an individual member of that type. It naturally follows that we cannot generalize from a study of one or two individuals of a given type. I think it is also clear, from what has been said, that we should not expect to find many laws which are universal in their applicability. It has been demonstrated on several occasions that there may be a very high degree of correlation between two given structures in one racial type, and only a very loose correlation between the same two structures in another racial type.

The reason that our results are discordant with those of the comparative anatomists is that they have spoken of the skull as a whole. Dolichocephaly and brachycephaly have not been confined to the brain-case. The length of the head has been measured in such a way that it includes the face, and consequently the palate. The correlation, as stated by them, has been spurious.

If we examine the data of Oppenheim⁽⁵⁾ on a fair series of primate crania we find the same discordant results we found for man himself.

TABLE IV.—COMPARISON OF PROPORTIONS OF ALVEOLAR ARCH WITH PROPORTIONS OF BRAIN-CASE. (A large index denotes a relatively wide, short head, and a wide, short arch respectively.)

| Primate. | Cranial index. | Maxillo-alveolar index. |
|---------------------|----------------|-------------------------|
| Hapale | 72 | 108 |
| Lemur | 73 | 68 |
| Cebus | 76 | 96 |
| Cercocebus | 79 | 67 |
| Hylobates | 79 | 77 |
| Theropithecus | 80 | 60 |
| Cynocephalus | 80 | 67 |
| Mycetes | 80 | 82 |
| Semnopithecus | 82 | 92 |
| Gorilla | 82 | 65 |
| Chimpanzee | 84 | 81 |
| Macacus | 85 | 73 |
| Orang-utan | 88 | 75 |

Hapale shows the longest brain-case and the shortest alveolar arch. Cebus shows the same condition in a less marked degree. Macacus, Gorilla, and Orang show a relatively short, wide brain-case and a very elongated palate. The following table shows the relationship of the absolute measurements; the most constant relationships are in the measurements of breadth:

TABLE V.—COMPARISON OF ABSOLUTE MEASUREMENTS.

(The diameters of the palate are expressed in terms of percentage of the diameters of the brain-case.)

| | Palate length to brain-case length. | Palate width to brain-case width. | Palate width to face width. |
|---------------------|-------------------------------------------|-----------------------------------------|--------------------------------|
| Hapale | 41 per cent. | 61 per cent. | 56 per cent. |
| Cebus | 46 " " | 58 " " | 50 " " |
| Semnopithecus | 54 " " | 58 " " | 48 " " |
| Lemur | 85 " " | 77 " " | 58 " " |
| Hylobates | 62 " " | 60 " " | 50 " " |
| Mycetes | 80 " " | 81 " " | 54 " " |
| Macacus | 75 " " | 64 " " | 50 " " |
| Cercocebus | 80 " " | 63 " " | 47 " " |
| Chimpanzee | 58 " " | 56 " " | 45 " " |
| Cynocephalus | 82 " " | 62 " " | 45 " " |
| Orang-utan | 76 " " | 64 " " | 42 " " |
| Gorilla | 75 " " | 60 " " | 39 " " |

It would seem, then, that the principle of dolichocephaly and brachycephaly, in itself, is not sufficient to explain the variation in the form of the alveolar arch. The statement has been made that the teeth conform to the skull rather than the skull to the teeth. It is clear that if we would accept this statement we must distinguish between the brain-case and the facial skeleton. All parts of the skull are not necessarily in harmony. In dealing with the individual, at least, it is apparent that the face may vary independently of the brain-case. As to how far the face determines the teeth or the teeth the face I am not prepared to state. It does not seem essential to say which is the cart and which the horse. It is safer to say that the dental arch and face vary together in respect to width.

This subject presents opportunities for the orthodontist to render service to anthropology. In your research on teeth you can add to our knowledge if you would attempt to study them in relation with other parts of the body. That there are possibilities has been shown by Mr. Leslie Spier of the department of Anthropology in this museum. In a study of a series of palate casts, collected in

Porto Rico by Prof. Franz Boas, Mr. Spier has shown that the teeth may serve as an index of physiological development. His results show that individuals who are slow in erupting a given tooth are likewise behind their fellows of the same chronological age in stature and weight. In a recent number of the DENTAL COSMOS a practitioner has called attention to an apparent susceptibility of blond individuals to dental caries. Such subjects are deserving of more detailed study.

SUMMARY.

The principal points I have attempted to make may be summed up as follows:

Racial differences do exist. There are differences in tooth form and in the proportions of the dental arch. There is no

a priori reason to assume that these differences occur sporadically, and are not confined to racial or morphological types. The subject deserves more detailed study before it is abandoned.

It should also be borne in mind that the loose generalizations of comparative anatomists and anthropologists are of little value to the practitioner except in so far as they may furnish him a broader point of view. Apparent correlations within a group are not necessarily real when applied to the individual. Absolute interrelations are rare in biology, as are also principles which are universal in their applicability. In our conclusions on cause and effect we should remember that the variability and plasticity of the individual are modified by factors of growth and the determinants of biological types.

Finally, I believe physical anthropology offers much to orthodontia in the way of methods. The differences with which you are dealing are so slight that they necessitate accurate mathematical treatment and description. Such statistical treatment should be a means to an end, and not the end. In other words, we should use mathematics as a means of describing more accurately and determining the extent of the relationship between different parts of the body, but we should not look to the human body to provide us with mathematical problems as such.

In conclusion, I repeat my belief that both sciences can profit from a closer co-operation between orthodontists and

anthropologists. The collections of the American Museum of Natural History are always at your disposal for study. We are always ready and willing to co-operate with you in any possible way to further scientific research.

Importance of Dental Supervision During Pregnancy.

By J. CLARENCE SALVAS, D.D.S., Philadelphia, Pa.

(Read before the Academy of Stomatology, at its regular meeting held January 4, 1918.)

THE two following communications from physicians serve to illustrate the difference of opinion with regard to the care of the mouth and teeth during pregnancy:

Dear Doctor,—Mrs. A. informs me that she is suffering from a back tooth. As she is pregnant I advise her that she must not visit the dentist or have anything done to her teeth, unless it be merely to relieve the aching tooth. You understand the seriousness of the situation, and therefore if you will avoid doing anything but what is absolutely necessary to make her comfortable I will greatly appreciate it.

Yours truly,

December 5, 1913.

My dear Doctor,—I am sending Mrs. B. to you. I wish you would attend to the condition from which she is suffering. As near as I can make out it is the upper second molar. Please note the condition of the gums; probably you can suggest a remedy to relieve the excessive bleeding, which while not harmful to her, is very annoying. She has just come from her family dentist, who refuses to assume any responsibility, and confines his treatment to stuffing cotton in a (rotten) tooth, and expects it to remain there for three months. I beg to remind you that I am responsible for mother and child. You keep her mouth and teeth healthy and you will be a valued co-worker in this case. Nothing is more exasperating than dental disorders during the weeks when a woman is con-

fined to her bed, in more or less of a critical condition.

Yours truly,

March 2, 1914.

These two communications need no comment. They speak for themselves. We cannot but be impressed, however, with the fact that our modern understanding as to the proper treatment of the mouth and teeth during gestation is very different from what it was some years ago, when it was the general belief that the mother must sacrifice a tooth for each child—a preposterous thing to say the least, but the impression was so strong in the medical and dental professions that it finally communicated itself to the laity. This has been a most difficult fallacy to dislodge, not only from the minds of the profession but the laity as well, and has led to the loss of a great many teeth which might otherwise have been saved, to say nothing of pain, general discomfort, and bad hygienic conditions that might have been avoided. During the past few years I have had a great many of these cases, many of which were attended in conjunction with the obstetrician in charge of the case.

Clinical observations lead me to classify the conditions prevalent during gestation into two classes, each requiring specific remedial measures, and each being due to entirely different influences.

First: The environmental conditions

produced by vomiting during the first months of gestation, which is the period of susceptibility to caries. There is little or no gingival inflammation, or hypertrophy, or congestion of the gum tissue.

The treatment calls for the most stringent preventive measures and the maintenance of a vigorous oral asepsis. The sulci of the teeth, the interproximal spaces, and the free margins of the gums, become filled with masses of organic matter which rapidly undergo putrefaction and fermentation, creating an ideal medium for the inception of dental diseases. The importance, therefore, of prompt, vigorous attention is obvious. My first treatment, therefore, is confined to thorough prophylaxis, scrupulously removing all deposits and polishing the surfaces of each tooth, using the orange-wood points charged with finely powdered silex and sodium bicarbonate. This is followed with a warm solution of iodine and potassium iodide, used as a spray under high pressure; through its germicidal properties this solution destroys the spores and parent cells in albuminous material, which it readily penetrates, and stains any remaining bacterial plaques. This first treatment is concluded with a vigorous massage of the gums, using the index finger and the thumb and a paste of equal parts of sodium bicarbonate and boric acid to which has been added cinnamon water and a few drops of myrrh.

Vomiting during gestation seldom occurs after the fifth month, but during this time weekly treatments are arranged, wherever possible, or until the conditions are under complete control, when they may be given monthly. The second treatment is given the following week, when prophylaxis is again instituted, and the mouth and throat sprayed with a warm salt solution to which has been added a little vinegar. This solution is most effective in removing from the oral cavity and throat mucus or mucin that has become saturated with particles of decomposed matter. A searching examination is then made. Devitalized teeth are radiographed, carious tissues are

carefully treated, and all weakened or threatened surfaces protected; that is to say, the deep sulci of the molars and bicuspid, after adjusting the dam, are washed with absolute alcohol, sterilized with phenol, and black copper cement is packed in to one-third of their depth. Should the lingual surfaces of the molars and bicuspid manifest any signs of impending danger, as they frequently do, they are coated with a sticky mix of white copper cement. I have a number of cases at present where the buccal and labial surfaces of the incisors, cuspids, bicuspid, and molars have been treated in this way. It is astonishing how long cement smeared on the surfaces of the teeth will sometimes last.

Second: In the next classification, or where there is no vomiting, the systemic condition is manifested orally by hypertrophy or tumefaction of the gum tissues. At times the congestion is so great that the tissues will cover the entire labial surfaces of the lower incisors and bicuspid, and the impact of mastication will cause marked hemorrhages. In these unusual conditions it is necessary to limit prophylaxis to the parts of the mouth not affected.

The treatment consists first in inducing artificial arterial hyperemia, which is best accomplished by massage. I might add here that no treatment is so valuable as massage for improving the blood supply, for encouraging metabolism, in short, for toning up the tissues, which means in other words a checking of the waste and the establishing of that vital resistance necessary to resist bacterial activity. The tissues are then touched with 20 per cent. silver nitrate. The excessive swelling is best controlled with trichloroacetic acid, merely touching the margins with the small point of a wooden pick dipped in the drug, and traced along the margins of the swollen gums. After from three to five treatments the venous engorgement disappears, and the tumefied gum tissues due to stasis will give place to normal. In these conditions there is no exudation or involvement of the pericemental membrane, and when the conditions are once under control

they can be kept in check by monthly prophylactic treatments.

Strange as it may seem, these two conditions—that is, the hypertrophied and congested condition of the gums and the decalcification of the tissues of the teeth during the months when nausea periods prevail—do not appear in the same mouth. It is either one or the other, and in a greater or less degree. I have come to believe, however, that the keynote to the whole situation is the alteration or creation of conditions surrounding the

teeth, rather than any functional disturbances in the organic structure of the teeth themselves, and while we do not know all we should about the conditions which influence these oral manifestations during pregnancy, yet we are certain of one thing, that strict and vigorous prophylaxis is favorable to the limitation of dental disorders.

The Conservation and Utilization of Cicatricial Bands in the Treatment of Jaw Fractures Involving Extensive Loss of Substance.

By MM. GERNEZ and LEMIÈRE,

CHIEFS OF MAXILLO-FACIAL SURGERY AND PROSTHESIS OF THE THIRD REGION, FRANCE.

(Abstract of a paper published in *l'Odontologie* for February 1918.)

THE authors describe three varieties of cicatricial bands which are most often formed in connection with extensive tissue destruction around the jaws:

(1) *Intermaxillary bands*: Bands between the maxillæ and mandible.

(2) *Interfragmentary bands*: Bands between the bony fragments.

(3) *Intermandibulo-tegumentary bands*: Bands between the mandible and the skin.

Contrary to the ideas generally accepted before the war, they propose a form of treatment having for its purpose both the preservation and even the encouraging of the formation of these tissues, which formerly it was sought to eliminate.

These neoformations, in their deep parts, are utilized together with mechan-

ing, in general, firmer pseudo-arthroses, the masticatory forces are better co-

ordinated, and the esthetic results are more satisfactory.

Report of a Case of Follicular Dental Cyst.

By R. E. DENNEY, D.D.S., Philadelphia, Pa.

(Read before the Academy of Stomatology of Philadelphia, at its regular meeting, January 4, 1918.)

I HAVE been asked to report a case of follicular dental cyst in the mouth of one of my patients, a boy of ten, that came under my observation recently. He was brought to me because of a slight swelling on the right side of the face, which his mother attributed to some dental cause. There was a history of a dental abscess in this region about a year previous, following a blow on the face, but at this time the abscess had disappeared. The swelling was first noticed by the mother about a month previous to

her consulting me. About a week before, there had been a profuse hemorrhage from the nose. There had been no pain but the swelling and the hemorrhage prompted her to seek treatment.

Upon examination I found that the swelling extended from the upper right deciduous cuspid to the first permanent molar. Above the deciduous cuspid there was a fistula much larger than we find in connection with ordinary dental abscesses, with the appearance of having an active discharge from it, although

upon pressure on the hardened swelling there was no discharge. In looking about for a cause, the only tooth I could suspect was the second deciduous molar, which had been devitalized and filled. The first bicuspid was erupting. The deciduous cuspid above which the fistula was located was unfilled, and apparently normal. As the time was approaching when the second deciduous molar and the deciduous cuspid would be shed, I extracted them, hoping that one of these might be the cause of the trouble, but as I did not feel satisfied that they were the sole source, I had the patient return in three days. The swelling still appeared to be about the same, as did the fistula. I then had roentgenograms made, and found a cyst extending from above the deciduous cuspid back to the first permanent molar. The unerupted second bicuspid, which was calcified to a point just above the crown, was turned almost upside down from the pressure of the cyst, the occlusal surface pointing upward. The partly developed root of the first bicuspid projected into the cyst cavity, a layer of bone about the thickness of the crowns of the teeth holding them in place.

I referred the case to Dr. Thomas Aller for operation. He found the cyst had cut off practically all nourishment from the two bicuspids, and removed those. He also found something the roentgenograms did not clearly show, namely, that the partly developed cuspid lay entirely within the cyst cavity, and it also was removed. The lining of the cyst was removed in one piece, thus preventing recurrence. I saw the patient about two weeks after the operation. Dr. Aller in the meantime treating the case, when I found that the cavity had closed somewhat but was still quite large, the lower part of the opening being about the size of the end of my first finger, and connected through the antrum with the nose. This was evident from the boy's

speech, and from the discharge of mucus into the cavity. I also found a large unmasticated pea well up in the cavity. This suggested the necessity of some appliance to prevent the impaction of food in the cavity, so I made a small vulcanite plate extending from the lateral to the first molar carrying three teeth to replace those that were lost, and held in position by cast clasps around the molar and the lateral, being careful not to have the rubber extend into the cavity and prevent its closing.

I saw the case recently, six months after the operation, and the cavity had healed perfectly. The mother said that it had completely closed in four months, and the spraying had then been discontinued.

The operation was a success and the patient lives, but three teeth that should have been perfectly good are now lost beyond recall. We know that a follicular dental cyst is a sac lined with epithelium, filled with fluid and containing a normal or abnormal tooth, and is the result of the abnormal development of the dental follicle. What causes the abnormal development we are by no means sure, nor do I feel that I can add any definite information on that point. But when we have a history of a dental abscess in this same region, when there is present a devitalized tooth which could be the only cause of that dental abscess, and the area that this dental abscess has occupied being within the area occupied by the cyst, the finger of suspicion points accusingly to that devitalized tooth as the starting-point of the cyst. This should cause us to view with much distrust the practice of retaining for orthodontic or other reasons deciduous teeth or roots of deciduous teeth that we definitely know to be diseased.

Traumatism Due to Faulty Co-ordinating Bridge Work.

By PAUL R. STILLMAN, D.D.S., New York, N. Y.,

DIRECTOR OF INSTRUCTION IN THE DEPARTMENT OF PERIODONTIA, COLUMBIA UNIVERSITY,
NEW YORK.

(Read before the union meeting of the District of Columbia Dental Society and the Maryland State Dental Association, Baltimore, June 6 to 8, 1917.)

THERE is an ancient adage which bids the cobbler stick to his last, which axiom is founded on common sense. It might likewise appear that a specialist in any particular branch should refrain from criticism of other branches of his subject; that he should adhere to his own line, leaving to others who have practical knowledge and experience any expression of disapprobation. But while the cobbler may not be a tanner, he must be able to recognize and procure good leather in order to successfully ply his own trade.

In these days of many specialities it is difficult to draw a positive line of demarcation, so constantly do our subjects overlap and so close is their interdependence. The periodontist beginning a case must accept or reject much that is the work of specialists in other branches, and it is the shortcomings of the results in bridge-work restoration which he most frequently finds deplorable.

A realization of the growing importance of the subject of the reciprocal relations of the jaws, the occlusion of the teeth as it applies to every dental prophylactic measure and to the articulation of bridge work in particular, is my justification for this paper.

It is quite the universal custom among those who make bridge work to ignore the practical application of those accurate measurements of the jaws which are so necessary to successful results in all dental restorations.

The theoretical principle of substituting for lost natural teeth certain artificial

appliances by attaching them to healthy abutment roots is undoubtedly sound. It is the ultimate idea, in my opinion, for the restoration of dental function. That cases so treated are followed by disaster, that they are productive of disease, and even death, does not prove that the idea is fundamentally incorrect.

In every form of scientific discussion differences arise as to that which is correct and that which is not. The tests of time and usage will in the end show favor to one idea or principle, to the exclusion of all others. This is as it should be, for it is by our allegiance to that which has proved good in both theory and practice that scientific advancement is made possible.

The practice of crown and bridge work is at present undergoing a very commendable revolutionary stage in its development. New systems and technique have been introduced by various men who have recognized the necessity for greater cleanliness in mouths where bridges were a necessity. Certain forms of removable bridge work appear to have solved the problem of sanitation. Conservation of the normal pulp and the construction of supplied dummies which represent true anatomical tooth forms is yet another most commendable advance. Nevertheless the utterly inefficient and worthless type of fixed bridge represented by a row of flat-back porcelain facings suspended between two-piece shell or Richmond crowns is still a familiar sight. This type of bridge, with its grotesque occlusal surfaces, has always been a men-

ace to hygiene, and the only excuse those who still produce such bridges can offer is that they were taught the method in their college days twenty years ago.

The periodontist cannot with propriety criticize adversely any of the several types of bridges or crowns which are approved by the authorities on this subject, nor the methods and systems of procedure which enter into their construction. It is not the intention of this paper to open discussion on any other phase of bridge or crown restorations than that which, in the co-ordinating relation of the jaws in the function of mastication, causes trauma of the pericementum and its pathological sequelae.

PROPER OCCLUSION A NECESSITY IN BRIDGE WORK.

There are certain fundamental essentials in bridge work which apply equally to all operations for the restoration of lost occlusal surfaces of the teeth, whether by bridges, crowns, inlays, fillings, or plates, viz, that the occlusal surfaces which are supplied must co-ordinate with the antagonizing surfaces in the opposite jaw. Nature has produced for us the plans we are to follow in the restorations which we make for the teeth, and she protests against such work as does not prove up to her requirements, or when these restorations violate her laws, by instituting certain pathological processes in the supporting structures.

That there is a physiological movement of the teeth in the alveoli during normal function is generally admitted; the investing structures are singularly elastic, otherwise attachment by ankylosis in primates would be fatal. That there is a movement of the teeth during the function of mastication accompanied by malacia is also here affirmed. The normal movement is physiological, always slight, does not increase, and is necessary to prevent fracture when marked stress is applied in the occlusion; while the latter is pathological, and is frequently accompanied by evident rarefaction and dental periclasia. The physiological movement of the teeth is not easily dis-

cernible, as the change of the approximal relation is extremely slight, even when considerable force is applied. The pathological relation or traumatic occlusion is easily discernible; it is a relation due to a faulty co-ordination of the occlusal surfaces. The term traumatic occlusion has been defined by the American Academy of Periodontia as follows—"A perversion of the occlusal relations of the teeth when in use, whereby an excessive stress is brought upon one or more antagonizing teeth." It is an acquired condition, and among other phases is the one I wish to bring to your attention tonight. It may be acquired at the time of the insertion of bridge work and inlays, and is always as fatal in the one case as in the other unless the proper relief is obtained.

The prosthodontist finds that any violation of the laws of dental articulation which has to do with co-ordination in function is fatal to the practical success of the artificial denture. Certain difficulties were encountered in the old days, prior to the introduction of anatomical articulation, chief among them the embarrassing knowledge that a plate would adhere to the mucous membrane surfaces upon which it was intended to rest only so long as the mandible was passive; just as soon as the function of mastication was attempted the plate would become confused with the food bolus, and this resulted in a mastication of teeth instead of *by* teeth, as was intended. Many of these dentures, which in their adaptation to the mucous surfaces were valve-tight as to fit, showed a perverse instability when put into service.

The bridge worker encounters no such unsteadiness after cementing a bridge to place. The bridge is set securely upon two or more abutment teeth or roots, which are presumed to be in normal health. Dynamic stress even at this time is discernible. It is not to be expected that a bridge will gyrate as will a plate, which has no abutments to hold it in the mouth; not for a while at least, not until these abutment roots have been literally broken from the alveolar process through exactly the same incorrect mechanical stress relation as in the case of the plate.

The exodontist really believes that a vast majority of teeth are diseased, and should be extracted, for it is his experience that most cases which are referred to him actually do need such treatment, while the periodontist seldom sees a case of dental periclasia having bridge work but that it is necessary to remove—and thus destroy—the bridge in order to proceed with the treatment. Many a handsome and exquisitely made bridge has brought a smile of virtuous pride to the operator and of satisfaction to the patient when it was cemented to place, but there are no laughs and congratulations passed around when the abutments of the bridge have been finally destroyed through septic periclasia, and it falls into the hands of the periodontist for removal.

USE OF THE ANATOMICAL ARTICULATOR IN BRIDGE WORK.

The specialty of bridge work seems to be noticeably unorganized, and the methods of practice quite empirical. Other branches in dentistry which require special talent and training both in the academic and technical aspects, such, for instance, as orthodontia, radiodontia (roentgenology), periodontia, etc., have their own organizations which are devoted to the advancement of their several branches; they have journals and published proceedings of their meetings which are national in their scope, and which exert a wide beneficial influence toward a unification of ideas and a standardization of technique. There are nearly a dozen men of my acquaintance who make bridge-work restoration the major branch in practice, yet their individual ideas as to what should be accepted as standard and what should not would represent almost as many separate ideas as there are individual practitioners. There may be many, I hope there are, who construct all bridges and crowns upon the anatomical articulator, and who practice the same scientific methods in producing co-ordination in the occlusal relations of bridges as do those prosthodontists who construct full dentures upon the principle which Gysi has exemplified

for dentistry. I repeat, there may be many, but, if so, the fact has never been brought to my notice. In the case of bridge workers it would appear that the necessity for the proper use of the anatomical articulator seems to be less important to them in an inverse ratio as it appears important to the periodontist.

The scientific procedure of anatomical articulation is a standard method of determining just what the true relation of the teeth should be for each case. One who expects to accomplish satisfactory results in bridge work should discard the antiquated "rule of thumb" in articulation, and apply these scientific principles. He should adopt the anatomical articulator, with its possibilities for accurate measurements, in ascertaining the true relation of the condyle path to the plane of occlusion. He should apply the face-bow, which will determine just where the casts upon which he expects to build a bridge must be placed in relation to the measurements from condyles to incisors, and he should never set any bridge where co-ordination of the occlusal surfaces of the teeth in mastication has not first been fully proved to be accurately normal.

The prosthodontist who does not employ this method in the construction of a denture will have a very high percentage of failures. To be sure, the steps necessary for the construction of a plate upon these principles increase somewhat the expense of production, but the constant necessity of remaking cases which have resulted in failure becomes almost *nil*.

DENTAL PERICLASIA THE RESULT OF TRAUMA.

Dental periclasia has its most frequent and immediate contributing factor in trauma of the pericementum, trauma which is communicated to the investing tissues by an improper relation of the teeth in occlusion. These vascular investing tissues depend upon cell regeneration—a never-ending metabolism—for their existence. When trauma is induced the food supply to these structures

is inhibited, malnutrition and unbalanced waste-removal follow, vital resistance is lowered, and any break in the integument at the subgingival space is quickly followed by infection.

Normal tissue never becomes infected. There must first occur certain changes which make the tissue pathologically receptive, as well as some break in the integument where the infecting organisms may enter. This is true in regard to the infection of tissue which supports the teeth, as elsewhere in the body. In traumatic occlusion the elastic gingival attachment of the dental ligament becomes gradually weakened, and finally literally torn from the cervical cementum, opening the subgingival space for the ready entrance of detritus. In such an environment the mouth flora find an ideal culture medium and a ready passage. Normal gingival epithelium has a very high resistance to all micro-organic life, as have all the mucous surfaces of the whole alimentary tract; but when these structures have sustained a prolonged irritation from a constant and determined pounding with every closing of the jaws they become exhausted, and the natural resistive forces are found too debilitated and disorganized to repel attack. The symptoms of occlusal trauma are to be observed in mouths perhaps years before the resistance of the investing structures have become so lowered that they become a prey to infection.

The mouth may at times be utterly neglected in so far as its sanitation is concerned, it may even tolerate the presence of badly fitting crown bands, with their usual accumulations of septic debris, such a state being endured for years without evidence of periclasia, but let a beautifully carved occlusal inlay or filling be inserted, where zeal for the artistic has resulted in an abnormal cusp relation, or let a piece of bridge work or a single crown be placed in such a mouth and the reciprocal relation of the occlusion disturbed, and forces are at once set up which result in tissue dystrophy and infection. This would indicate that the immunity of these tissues was sufficient in the one case, where the resistance was

high, due to the normality of the occlusal relation, and insufficient in the other, where the abnormal stress relation with its accompanying interference with co-ordination has reduced the tissue resistance by traumatic occlusion.

Periodontists find bridge work of every conceivable type in the mouths of their patients. A description of some of this should be suppressed, as considered unmentionable in polite dental circles; we will therefore let it pass. A reasonable percentage of this work, however, reveals at a glance that it is the work of the earnest, skilful, and painstaking type of practitioner who comprises the large majority of our profession. Let me present a typical case: Overlooking for the moment the well-nigh fatally diseased condition of the stumps which are acting as the holding abutments, let us observe the bridge itself. One can well imagine the satisfaction of the dentist when the piece was received from the laboratory quite finished and mounted upon the little plaster-of-Paris cast representing the segment of the jaws which was so generously included in the impression. One can see at a glance that the porcelain facings are not checked, nor has the solder, which has been so skilfully flowed over the backings and the conventional occlusal swagings, any pits or blowholes. The reinforcement by extra plate and solder makes the shell crowns rather difficult to remove. There is an evident honesty throughout its whole composition. The shade selection of the porcelains is excellent and these have been ground to fit the gum contour with precision. The buccal resemblance to teeth is striking. This seems as far as we can go in commendation or compliment, for the occlusal surfaces are quite untooth-like in both outline and form. And the lingual surface—there is no lingual surface! From the lingual cusp to the buccal cervical border there is just a smooth inclined plane to encourage the tongue in its efforts to dislodge food particles. This surface has been called a self-cleansing surface, an example of misnomer of the most pronounced type. Study models of such a case would reveal that all of the

occlusal contact stress had been concentrated upon the bridge, for the abutments are loose and elongated, due to a thickening of the pericementum by occlusal trauma; they are also septic. It is today a professional crime to set a bridge such as I have described. Infection about the abutments must as inevitably follow in this case as in that of the tooth with a root-canal, which has been filled with absorbent cotton. This particular kind of result in bridge work is the outcome of unquestioning allegiance to antiquated methods, together with a disregard and ignorance of the anatomical movements of the mandible.

The making of study models as a forecast of treatment in restoration is a common practice among many of the more advanced practitioners. These study models are typical orthodontic casts, which are occluded in their true relations. Prognosis for the necessary anatomical restorations may thus be studied at leisure, and the scheme definitely decided before treatment is begun. The taking of impressions of finished cases for the purpose of making casts for criticism of one's own results is a practice which is indulged in by a very few; yet were this a customary practice, what an infinite improvement would soon result! Diagnosis for prophylaxis in such cases as these would reveal traumatic occlusion, if present, and much harm could thus be prevented. Were the results of these failures of bridge work through this fault apparent after a few days or weeks instead of after several years of unsatisfactory service; were the symptoms which are induced of a painful and inflammatory character from the very first, this paper would never have been written—for, like the prosthodontist, the bridge worker would have definite and immediate trouble on his hands, and the remedy would have been adopted simultaneously with its introduction into the plate work.

LIMITATIONS OF THE DENTAL LABORATORY.

The practice of employing laboratory assistants or of sending cases to the pub-

lic laboratories is good, provided one obtains competent workmanship. It must be remembered that these so-called mechanical dentists can only supply technical help; that they have no academic knowledge of the anatomy of the parts which are undergoing repair, nor do they even have an opportunity to observe in practical service the appliances upon which they work. That they frequently have skill in their work which exceeds that of the dentists who employ them is obvious. But so has the bricklayer superior technical skill to that of the architect, and so it should be. That the laboratory man's results are ever a failure is largely the fault of those who employ him. It has been said of the alarm clock that to be successful with its use one must know more than the clock.

In investigating the relation of the dentist to the public laboratory I have found that it is customary for the dentist to send to the laboratory impressions which include never more than the lateral half of the jaw; that the articulator used is of the hinge principle type, or else what is known as the "back extension" is used in place of an articulator, the latter having but one movement, lifting apart as a cover lifts from a box.

It is necessary, in order to obtain results which are satisfactory, to have a full impression of both jaws, and to have the casts poured in some material which has sufficient hardness on the occlusal edges to withstand attrition while the case is being articulated. The antagonizing cast should never be made from a wax bite, but from a cast made from an impression, and the upper and lower casts then assembled upon the anatomical articulator with the aid of the face-bow.

REQUISITES OF PERFECT BRIDGE WORK.

Bridge work should resemble the natural teeth in so far as it is possible. Correct measurements of the crown diameters should depart from the true measurements but slightly, if at all. Lingual surfaces are of greater importance to the function of mastication than the buccal and labial, and they should

be reproduced with greater care. Where there is great loss of alveolar tissue in the bicuspids and molar region, lingual roots should be carved upon these surfaces to lighten the weight of thickness, never departing from the true anatomical forms which nature has adopted, and

successful restoration of these lost teeth these facts should be ascertained and taken into consideration. Normal arrangement of the teeth in bridge restoration will not be tolerated in certain cases of this type when the maxillary habit is greatly interfered with.

FIG. 1.

FIG. 2.

which are fundamentally the correct ones.

The anatomy of the temporo-mandibular joints varies in every individual, as does the shape of the ears of each individual head. Its development as to form is greatly influenced by the erupting ar-

There are certain names to which credit for research in this work should be given, for it is by the labor of such men as Bonwill, Snow, Gysi, and Williams particularly, and many others, that this science has been developed. The writer does not claim that there has been suggested here anything original, but he does assert that the anatomical articulator has been used in these cases and found successful.

FIG. 3.

The name of Peeso is almost as familiar to the bridge worker as is the work itself. Dr. Frederick A. Peeso has recently published a text-book entitled "Crown and Bridge Work," which is a complete working compendium for this field. If the plea which I have made here has not impressed you with the gravity of the situation, I can do no better than to quote from the writings of this master of the subject. He states:

Another fundamental to crown and bridge-work success was brought to the fore when a few scientifically inclined earnest workers, in an effort to make more effective artificial dentures, began a careful study of the various movements of the mandible during mastication. The object of these efforts was to devise a contrivance to accurately reproduce these movements so as to enable the dental workman, when mounting artificial teeth, to secure a more normal occlusion. Heretofore if the upper and the lower teeth articulated

range of the natural teeth in their occlusal relations. Cases of unilateral deformities in malocclusion exhibit marked differences in the curve of the condyle path in this articulation. Certain maxillary habits are formed in each case previous to the loss of the teeth, and in any

with each other when the mandible was at rest, the work was deemed satisfactory, notwithstanding that the dentures were ineffective in mastication, owing to the fact that all the teeth met only when the mandible was in the rest position. At other times but few teeth were in contact. The immediate result of these investigations was a better understanding of the mechanism of mastication, and a higher appreciation of the importance of normal occlusion that has since reached all departments of our profession.

By occlusion is understood a rubbing or grinding surface contact of all the masticating surfaces of the teeth during all the movements of the mandible, as is always the case with the natural teeth in their normal position. Articulation is a mere fitting together in one position only.

This understanding of occlusion brought to the fore an imperfectly recognized cause of failure of many dental bridges. With the mouth closed, the teeth on these bridges fitted the opposing teeth accurately, but during mastication they touched at a few points only. Except for this fact these bridges might have given many years of excellent service, but owing to defective occlusion the force of mastication was concentrated upon a few teeth, which resulted in literally pounding the structure to pieces in a short time. In other cases the stress set up a destructive irritation in one or more of the supporting abutments, which just as surely resulted in the bridge failing. We know now that it is impossible for any one tooth to be unduly strained during mastication or other movements of the mandible if the occlusion of the denture has been properly adjusted, be it a plate, a crown, or a bridge.

This work of Peeso's is of such importance in the literature of bridge work that I will also take the liberty of quoting from this same source—from his chapter headed "Articulation." He states:

In crown and bridge work the question of the occlusion is of most vital importance, as the stability and life of the work depends to a very great extent upon its proper occlusion with the opposing teeth. In all cases of bridge work it is absolutely essential that only first-class anatomical articulators, capable of reproducing the natural lateral or triturating movements of the mandible, so necessary for perfect mastication, should be used. . . . Nearly all of the small so-called crown articulators on the market are absolutely worthless so far as securing good results are concerned. With these articulators the only movement possible is simply the up and down, or the opening and closing of the mandible. . . . In the majority of cases . . . the face-bow should be used to serve as a guide to mount models properly on the articulator.

The time has arrived when our profession is being looked upon as a group of scientifically trained men who have as their fundamental idea the prevention and cure of all disease which has its inception within the confines of the mouth. To be accredited with less would be ahorent to every ethical practitioner. To be *producers of disease* instead of physicians, to be *destroyers of teeth* instead of dentists, to be *artisans* instead of *surgeons*, is the very antithesis of our aspiration. So, if there has been a distressingly high percentage of failures in our bridge work, let us all get together and see that this stain on the escutcheon of the best profession in the world is wiped out. Let all among us who have at heart the high ideals of our profession either correct the practice of using a hinge articulator or quit making bridge work.

115 BROADWAY.

Indirect-Direct Gold Inlay Method.

By M. J. WAAS, D.D.S., Camden, N. J.

(Read before the Academy of Stomatology of Philadelphia, at its regular meeting, January 4, 1918.)

WHEN invited to appear before you this evening the suggestion was offered that I touch upon some "high point" of interest, and it occurred to me to speak about the "high point" usually present in gold inlays made by the indirect method, and a means of avoiding this.

Both the direct and the indirect methods have distinct advantages, and the method I wish to present to you, which may be called the "indirect-direct," I believe retains and combines the greatest number of advantages of each of the separate methods.

After the cavity is prepared it is given a very slight coat of lubricant, and a Roach cup of suitable size selected and trimmed to approximate shape for the case in hand. A piece of thick tin foil is placed over the hole in the bottom of the cup where the handle of the holder comes through so the impression material cannot touch it while hot and its removal from the cup after chilling is thus made easy. The shaped cup is then filled with softened impression material, preferably Lochhead's, and pressed firmly to place, where it is immediately hardened by a spray of cold air or water. This material hardens very quickly, takes a very sharp impression, and becomes so hard that one cannot remove it without fracture if there are any undercuts in the prepared cavity. Base-plate gutta-percha is then inserted in the cavity and the patient dismissed.

This impression is then invested in order that the amalgam model may be packed under pressure. A rubber ring is set on a glass slab, filled with quite

thick plaster, and the impression pressed down to place. It does not have to be invested deeply, as a small base is all we need with which to handle it. I use silver amalgam; any high-grade silver amalgam is suitable. In fact, copper amalgam can be used and may be re-used, but it is not so hard as the silver, does not stand the polishing so well, and leaves a deposit on the inlay. This deposit, however, can be removed in an acid bath; but I prefer the silver amalgam.

To begin the packing, the amalgam must be very soft, quite "sloppy" in fact, packed in small pieces, and the excess mercury removed by pressure, using bibulous paper. Drier amalgam is then added under very strong pressure and the well in the plaster filled level full. After the amalgam is hard, the rubber ring is slipped off, the plaster investment broken away, and the impression and amalgam model separated with the aid of hot water. The amalgam model is then washed with soap and water, dried, trimmed to shape, and the cavity painted with a very thin film of lubricant—castor oil 1 part, and glycerin 2 parts. It is then filled with inlay wax to approximately the proper shape.

This wax model is now removed from the amalgam and tried in the patient's mouth, trimming with a lancet at the contact point in a compound cavity until it goes to place. The contact with the adjacent tooth or teeth is now established, and from the fit it can be determined whether the original impression was accurate or otherwise. Then ask the patient to close the teeth together very lightly, and note where the wax

model is too high. Take a large egg-shaped burnisher, warm in the alcohol flame, and touch it to the high point in the wax. This softens the wax. Now have the patient occlude the teeth again, and repeat this until the wax model is entirely down. The occlusion is now established. Remove the wax inlay carefully, replace in the amalgam die, and carve to correct anatomical form.

The next step is to add a very narrow ribbon of wax over all the edges, melting it on with a very delicate spatula, being careful to avoid leaving any very fine feather-edges. This I consider quite important, as it gives a bulk of material over all the edges. When the wax is burned out, the gold very easily casts to all points, and the surplus can be removed in the finishing process. Place the sprue at some point where it will not mar the contact or occlusal surface, and cast. After casting, place the inlay in the amalgam die and swage to place with moldine. Burnish, disk, and polish, and the inlay will go to place a completed operation without the necessity of any further finishing in the mouth, if each step has been correctly carried out. One should be careful to hold the inlay firmly in place under considerable pres-

sure for three minutes while cementing to place, so that it will not be forced up by the expansion of the cement, and thus interfere with the occlusion.

By this indirect-direct method we have retained the advantages of the direct method in so far as we have established accurately our contact and occlusion in advance of casting, and we have gained the following advantages over the direct method:

We can carve the inlay to anatomical form very much better in the amalgam die than in the mouth, and do it at our leisure, without detaining the patient. We do not have to grind, disk, or polish it in our patients' mouths, for which they are always very grateful. We can see our fit, particularly at the cervical margin, in advance—something we do not see in the direct method in most instances; and further, an M.O.D. cavity, a very difficult one at best to make accurately by the direct method, becomes by this method just as easy as any other.

We have thus retained every advantage of the indirect method *plus* the fact that it has received in advance the approval of the supreme court of occlusion, the Mouth!

315 SOUTH FIFTH ST.

CORRESPONDENCE

A Case of Tooth Gemination.

TO THE EDITOR OF THE DENTAL COSMOS:

Sir,—The accompanying pictures illustrate a case of an unusual confluence of the lower central incisors. The patient is about forty years of age; mouth in fairly good condition. The teeth are all

crowns. Incisally, no line of demarcation is present, the incisal edge being perfect.

The lingual surface (Fig. 2) appears more like that of an upper central incisor, the cingulum being almost perfect.

FIG. 1.

FIG. 2.

present, except the lower third molars, which may be either impacted or altogether absent; the upper ones are quite diminutive. Articulation good.

Labially (Fig. 1) the confluent incisors show a slight line where the teeth have united. This line or groove is altogether absent in the incisal third of the

The patient had never been to a dentist, but his teeth, except for a slight deposit, were in good condition—a remarkable case of immunity.

Yours truly,

C. W. BATCHEFF, D.D.S.

CHICAGO, ILL., February 13, 1918.

DENTISTRY AND THE WAR.

Operative dental section of the American Ambulance Hospital of Paris, Neuilly-sur-Seine, France.

PROCEEDINGS OF SOCIETIES

Eastern Association of Graduates of the Angle School of Orthodontia.

Regular Meeting, held in New York City, Saturday, January 26, 1918.

A REGULAR meeting of the Eastern Association of Graduates of the Angle School of Orthodontia was held on Saturday, January 26, 1918, at the Museum of Natural History, New York City.

The meeting was called to order at three o'clock, by the president, Dr. F. T. Murless of Hartford, Conn., in the Osborn Library.

The PRESIDENT. Before taking up our regular program Professor Osborn will address us.

Prof. H. F. OSBORN. *Mr. President, and members of the society.*—It is a great pleasure to welcome you to the Osborn Library. I have just told your president that this is in a sense a baptismal ceremony, as this is the first meeting of any kind that has been held in this room since it has been enlarged and refitted.

In thinking over the purposes of your society, I recall the fact that my own first studies in teeth were made in the Royal College of Surgeons in London, with a wonderful collection which was brought together by the distinguished founder of British comparative anatomy, Dr. John Hunter. Hunter was succeeded by Richard Owen, and his studies carried on by Owen culminated in Owen's "Odontography." That was the pre-Darwinian period, a period in which teeth were considered as isolated types, with little idea of genetic relationships. I fancy the last

work of that kind was the volume by Dr. Tomes, with which you are all familiar—the last work, and a very conservative one, of the older odontography.

The foundations of the new odontography were really laid by Professor Edward Drinker Cope, in 1880, on large collections of teeth which include types that we estimate to extend over a period of three millions of years in the earth's history.

It is very striking that there is a uniform fundamental pattern running through these basal eocene teeth. They look extraordinarily alike in one important feature, no matter to what order of animals they belong, carnivores, herbivores, frugivores, or insectivores; it is this feature to which Cope gave the name *tritubercular*. Cope's studies then led him back to a brief survey of the teeth of early mesozoic time, many æons preceding the basal eocene epoch, and he conceived the idea that in the Jurassic epoch there were antecedent forms. He thus glanced at the sources of the tritubercular type of molar and also contributed to the knowledge of the evolution of the tritubercular type in other lines of animals.

I made a long journey to the museums of Europe to verify the mesozoic origins of the tritubercular molar. Trituberculy also fascinated me in studying some of the early types of primate teeth of the middle eocene epoch of North America,

and I was led to the paper entitled "Evolution of Mammalian Molar Teeth To and From the Triangular Type." That was my first expansion of the Cope tritubercular theory. It has been developed and applied to every order of the mammals by different workers, by Cope, Dr. Wortman, and myself, by Dr. Matthew of the American Museum staff, and notably by Dr. Wm. K. Gregory.

With the co-operation of Dr. Gregory my various essays and observations, extending over a long period of years, were collected into the volume entitled "Evolution of Mammalian Molar Teeth," and I take great pleasure in inscribing a copy of this volume to each member of this association, in memory of your assemblage here and as an indication of the welcome which we extend to you and the pleasure with which we anticipate the results of your researches.

Mention of the names of a number of physicians—John Hunter, Joseph Leidy, and Richard Owen himself, who was trained as a physician—is of interest because it shows that in the early days comparative anatomy was the avocation of the physician, which led him away more or less from his professional studies into new scientific directions.

There has been unfortunately among students of human anatomy heretofore not sufficient recognition of the value of comparative anatomy, and similarly among comparative anatomists an insufficient recognition of the great value of the opportunities afforded to men like yourselves in human anatomy and human odontology. I understand one of the objects of this meeting is to bring together the two lines of study and observation, human and comparative, which have been so long divorced, and I am sure it will be pregnant with very important and interesting results.

THE PRESIDENT. I am sure we all appreciate the hearty welcome Professor Osborn has given us, and am confident we shall each be pleased to receive his book, and shall treasure it.

Dr. GOUGH. I move a hearty vote of thanks to Professor Osborn, not only for

his book, but for the talk he has given us this afternoon. (Motion carried.)

LOUIS R. SULLIVAN, M.A., then gave a lecture on "The Bearing of Physical Anthropology on the Problems of Orthodontia." (Illustrated by museum specimens.)

[This paper is printed in full at page 305 of the present issue of the Cosmos.]

DISCUSSION.

Dr. Milo Hellman, New York. I have nothing to offer in discussion that would add value to the paper itself. I wish nevertheless to express my appreciation of the subject and the manner in which it is treated. The method employed in the presentation of the data involved is in my estimation an inspiration to those who do research work. I have done a little bit in that direction myself, and therefore appreciate keenly the efforts of the essayist, for it is almost staggering to realize the amount of work entailed in the elaboration of a paper of this kind.

With reference to race, I may state that besides other physical characteristics, there is a certain type of occlusion prevalent among different races. For instance, in investigating the occlusion of the orang, it was found that there are two distinct types of occlusion: thus, the molar and premolar series occlude in a similar manner to that in man, under normal conditions, while the incisors will either be in an edge-to-edge relationship or the upper incisors will extend considerably forward over the lower.

In the description of primitive skulls many scientists utilize as an anthropoid characteristic the edge-to-edge occlusion of the incisors, conveying, of course, the impression that there is no other manner of incisor occlusion in the ape. This, however, is erroneous according to the above evidence.

In man, like conditions have been found to exist in different races. In the examination of a large number of human skulls, of the Mongolian and Indian races, the Mongolian dentition was found to exhibit a considerable overbite in the

incisal region. Sometimes it is not really extensive, but apparently very marked, because the lateral incisors of the upper jaw are invariably longer than in any other race. They usually occupy a position on a horizontal plane with the centrals and the canines, or even below that. This gives an appearance of considerable overbite, although the actual lapping of the upper teeth over the lower is not marked.

The Indian race, on the other hand, seems to exhibit an edge-to-edge bite almost universally. I have looked over between 2000 and 3000 skulls, and found this relationship to be almost characteristic of the Indian dentition. With the increase of age in the Indian, the edge-to-edge bite and the extensive wear of the teeth in general seem to produce an effect that would suggest the idea that the lower jaw is pushing forward. This manifestation is prevalent only in old age.

Also a difference in form of the glenoids and condyloids has been noticed in these two races. In the Mongolian, the condyloid process is narrow and long, while in the Indian it is oval, showing that they have a wider sweep of the jaw during functional activity. The glenoid of the Indian is consequently more shallow than in the Mongolian. These are, in the main, the characteristics observed that may be associated with the race.

In conclusion, I wish to state that it has been a considerable gratification to me to have heard this paper, and to learn the methods employed in the presentation of such scientific subjects. I am in hope that some day, with the help of Mr. Sullivan, I shall be able to bring to your attention some interesting material bearing on this subject.

Prof. H. F. Osborn. The conclusions reached by Mr. Sullivan are quite similar to the ones reached by Dr. Gregory in reference to the general harmonic lengthening or broadening of the skull. A very simple way of illustrating harmonic lengthening is to take a sheet of rubber and mark the principal points on the sheet: then draw that sheet out from the brachycephalic length to the dolicho-

cephalic length, and you will find a perfectly harmonic result: it will be proportionately elongated. While we do find in the lower skulls that there is that general harmonic tendency, there is local disharmony very often, so that you get the same results as Mr. Sullivan has pointed out here. You get those striking disharmonies which sometimes are local in the cranial vault.

Another point which is interesting to surgeons, is that in the harmonic broadening of the skull entire areas are involved—the bones are very much broadened in that region, and operators for mastoid troubles find much more difficulty in operating on a brachycephalic than a dolichocephalic skull. Surgical operators are influenced by that, and I have been told that operators dread to operate on a brachycephalic skull, because there is more breadth of bone there to go through.

Dr. W. K. Gregory, New York. With regard to the general correlation of proportions in the skull, I have noticed a number of cases among extinct races of mammals where a general antero-posterior lengthening of the skull, as Professor Osborn said, would show a more or less harmonious lengthening of all of the parts, including the dentition: but I have also noticed that it was not a uniform percentage of lengthening throughout the skull, but that some parts would elongate more rapidly than others—I mean in a chronological series, where you can trace the history of each part. In fact, in one case which I investigated thoroughly, I did not discover the same increment in length throughout the skull, but I found that some parts increase faster than others, which is what one might expect. In this race (*Dolichorhinus*) of herbivorous mammals, the face, palate, and teeth took a larger part in the general lengthening of the skull than the basi-cranial region. In a distantly related genus (*Telmatherium*) the skull as a whole was also lengthened, but the increments of the different parts were quite different from the first set. One would feel that while there is a general harmony between the different parts of

the skull, yet there is also a certain measure of individual independence of the several parts.

Mr. Sullivan (closing the discussion). As to harmony and disharmony, there has often occurred to me this probability in explanation of the case of the Eskimo, for instance. The Eskimos are undoubtedly Mongoloid in their affinities. Our conception of the original Mongoloid

was an exceedingly broad-headed and short-headed type. The Eskimo now has departed from that. The brain-case is increased in length, and the width has probably decreased, while the face has remained stationary. I think that is a plausible explanation, if the Eskimo is from the true Mongoloid stem, and if the true Mongoloid stem was brachycephalic.

(To be continued.)

Academy of Stomatology of Philadelphia.

Annual Meeting, held Friday, January 4, 1918.

THE annual meeting of the Academy of Stomatology was held in the Arcadia Café, Philadelphia, Pa., on Friday, January 4, 1918. The meeting was preceded by a complimentary dinner.

The meeting was called to order at eight o'clock, by Dr. William A. Jaquette, the president-elect. The president-elect and the following officers were installed: Dr. O. G. L. Lewis, vice-president; Dr. Arthur E. Bassett, treasurer, and Dr. W. Stirling Hewitt, secretary.

The minutes of the last meeting were read by the secretary and approved. The report of the Treasurer was then read, and on motion received. Drs. Casto and Curry were appointed as auditors. Dr. Frank Fox was elected as the new member of Council.

The report of the Committee on Component Societies of Philadelphia was read by Dr. HEWITT. The matter was referred to Council for action.

The first item on the literary program of the evening was an extemporaneous talk by Dr. O. G. L. LEWIS, on "Unusual Conditions Met With in Everyday Practice."

The President next introduced Dr. R. E. DENNEY, who read a paper entitled "Report of a Case of Follicular Dental Cyst."

[This paper is printed in full at page 319 of the present issue of the COSMOS.]

The next item on the program was a paper by Dr. M. J. WAAS, Camden, N. J., entitled "Indirect-Direct Gold Inlay Method."

[This paper is printed in full at page 328 of the present issue of the COSMOS.]

Dr. J. CLARENCE SALVAS presented a paper on "Care of the Mouth During Pregnancy."

[This paper is printed in full at page 314 of the present issue of the COSMOS.]

DISCUSSION.

Dr. Geo. C. Küsel. I was much interested in Dr. Lewis's talk regarding anomalies. I have also to report a case of a third molar with four roots. I do not know whether this is very uncommon or not, but I never before came across a case or read of one in the literature.

Dr. Salvas's paper was particularly interesting to me, because of my having practiced medicine previous to practicing dentistry. I listened closely to his paper to note if there were any distinguishing characteristic or any particular pathognomonic sign in the mouth during pregnancy that had escaped my observation in my years of experience. I was never able to discover such in my practice of medicine, and have not been able to do so in

the practice of dentistry. It seems to me that we meet the same conditions in pregnant women that we do in individuals who are not susceptible to that condition or in women who are not pregnant; so it appears to me that the same treatment that is accorded mouth conditions at other times should be given to them during pregnancy.

Another opinion with reference to the nausea and vomiting in pregnancy, which is rather a late view, is that they are entirely due to what we call anaphylaxis. It seems that there are certain diseases of the placenta, which have not before been closely studied. The placenta comes away and is thrown off; it is studied only by those particularly interested in pathology. The average practitioner disposes of the placenta as soon as he can. Later observers seem to feel that there is some condition of the placenta that causes this condition of nausea and vomiting in women.

As to the influence of dental operations on pregnant women, it seems that when we realize that many women are more susceptible at that time to other conditions than they would otherwise be, we need not be surprised at their being more affected by dental operations than at other times. A patient once told me that when she was in that condition and did not want to have a child, she used to ride up and down Broad Street on the omnibus—in the days when the street was paved with cobblestones—and that this always had the desired effect! If such a thing as that would bring about such a result, we can understand how a prolonged dental operation might have a similar effect; but usually we can meet our patients and assure them that they will go through the period all right with the attention we give them.

Dr. H. B. Matteossian. There are several points that the paper of Dr. Salvas, however brief, seems to settle. One is the question as to whether dental treatment of any extent should be performed on women in a condition of pregnancy, and the essayist seems to be of the opinion, borne out by the majority of serious practitioners, that such work, when care-

fully performed, is not only possible but desirable.

The next point Dr. Salvas clears up is the question whether defects found in the mouths of pregnant women are of systemic origin or local conditions produced by hyperacidity and vomiting. The position he has taken is supported by those who have studied the question in recent years, the majority of whom believe that local conditions caused by acidity and vomiting and by changes in the secretions are causes of dental caries and of other abnormal phenomena in the mouths of pregnant women.

The use of trichloroacetic acid is very desirable. This remedy is not used to the full degree of its merits. It is not only mildly caustic, but has a stimulating effect; and the granulations produced by it are of a more healthy nature than are those produced by any other caustic in the mouth. It can be used to remove overhanging gum over the third molars, and in certain types of pyorrhea, with satisfaction, and the use of it as indicated by Dr. Salvas in cases of hypertrophy of the gums and bleeding in pregnancy will no doubt produce excellent results.

Dr. Küsel. May I supplement my remarks by stating that I have found that the use of paraffin that melts between 45° and 50°, or at 52°, which is the only kind procurable at the present time, is an excellent thing to massage the gums with. By its use we can get at places we are not able to reach by ordinary massage. I know of no material that is better adapted to the use of patients for this purpose than paraffin.

Dr. J. V. Mershon. I should like to call attention to a statement made in Dr. Denney's paper, that is, the one referring to the extraction of all infected roots of deciduous teeth. I see many suppurating conditions about deciduous teeth, and the opinion is prevalent in the profession that it is necessary to retain these teeth at all hazards, in order to maintain the space necessary for the eruption of the second teeth. I think that we have a duty to perform to these children that is greater than maintaining that space. In

the cases of the greater number of the children that come to my notice this fact has been brought home to me. I have seen a great many children taken with some form of illness; and immediately following that, an abscess forms on a deciduous tooth. Whether there is any connection between these two conditions or not, I do not know; but with the light that we have today on septic infection, it is fair to assume that there is.

I think that we have overestimated the value of retaining these deciduous teeth up to the full time at which the second teeth should take their place. The crowns of these second teeth are formed and well down long before it is time for the baby teeth to be lost; and with the premature loss of a baby tooth, the second tooth very rapidly springs up—at least, sufficiently to maintain that space.

About the only exception I can make to that is the premature loss of the baby cuspid teeth, especially the lower, but the lower baby cuspids are rarely found abscessed. So it is my practice to advise immediately the removal of all deciduous teeth that have not vital pulps. I think that probably the orthodontists have gone a long way toward establishing an undesirable proceeding in the dental profession in impressing on the dentists the necessity for retaining these teeth. While their general thought is correct, I believe there is a time when it is safe to lose the deciduous tooth, and when its loss will not interfere with the succeeding tooth. I think that is a matter that should be studied carefully by the men in dental practice who are handling children.

The meeting adjourned at 9.35 P.M.

Northeastern Dental Association.

Twenty-third Annual Convention, at Worcester, Mass., September 26, 27, and 28, 1917.

(Continued from page 250.)

FRIDAY—*Morning Session.*

(Continued.)

Dr. FREDERICK L. STANTON of New York City, presented a paper entitled "Engineering Principles applied to Dentistry," as follows:

Engineering Principles Applied to Dentistry.

By FREDERICK LESTER STANTON, D.D.S.,
New York, N. Y.

"The methods of diagnosis and operation common to the practice of orthodontia are unscientific and incomplete.

"The object of the practice of orthodontia is to establish normal occlusion

in mouths which exhibit malocclusion. Obviously the order of procedure in the intelligent practice of orthodontia should be as follows:

"A knowledge in each case of malocclusion of the form and dimensions of the occlusal arch which the teeth would exhibit when placed in normal occlusion. A demonstration of the malpositions contrasted with the correct positions. A plan to show the distance and direction of movement necessary to each tooth to establish occlusion. A knowledge of the forms, points of attachment, and action of the appliances which will best achieve the desired end. Some definite method of measuring progress and determining when the work is completed.

"The methods in general use in the practice of this specialty fail to meet every one of these requirements. They do not determine in advance the forms of arches which will effect correct relations of the teeth to each other in the same arch and of one arch to the other. Not one orthodontist in a hundred, if given models of upper and lower jaws showing malocclusion, can tell accurately, in advance, what forms of arches he will have to establish in that case to effect normal occlusion. He is compelled to go on the theory that if the arches are big enough to afford room for all the teeth, and the teeth appear to occlude in proper mesio-distal relations, normal occlusion will result and will be permanent. But, as will be shown, arches may easily be large in the wrong directions and deficient in essential directions, and nature will speedily undo his work and restore malocclusion.

"Not knowing what form of arch is necessary to restore normal occlusion, the dentist is unable to determine the distance or direction of movement necessary for the teeth, and is quite as likely to move them wrong distances or in wrong directions as in the right ones. The history of orthodontic cases contains many stories of wrong tooth movements.

"Under present conditions, the orthodontist is unable to select, to the best advantage, the teeth whose movements by him will induce the most advantageous results in other teeth, or the desired line of each movement, or even the point of attachment of the appliances which will effect the results with the least time and with the least effort and pain.

"The orthodontist is at present unable to determine his progress toward establishing normal occlusion. He can only tell such occlusion when the teeth have been fitted to place and he sees it accomplished. As they are only too often never fitted to place, he continues his efforts sometimes for years, not knowing exactly where he stands in the line of progress, but hoping that success may sometime happen. Sometimes it does; frequently it does not.

"These unfortunate conditions obtain

because the formulæ which guide orthodontists are not laws verified by exact observation and correct thinking and arranged into a rational system; they are mere observations, precepts, and rules."

I shall attempt to show you from the evidence that orthodontia is taught and practiced in violation of the simplest laws of mechanics.

The evidence is a *résumé* of my research work in conjunction with engineers. Dissatisfied with orthodontic results in general, and with the methods employed by our leading teachers in imparting knowledge, I decided to approach the problem by first equipping myself with a better understanding of collateral sciences. To this end a course of study was undertaken at Columbia College, biological department, on the subject of "The Cell," followed by a course on "Heredity." Contact with the teachers at Columbia changed my dental outlook on the subjects taught, and also suggested a new method of approaching the problem of malocclusion, namely, to borrow from engineering the practice of laying out on paper what you propose to do before trying to do it.

I now proceed to illustrate [exhibiting several slides]—(1) My methods of making dental maps by means of bisecting lines. (2) The dental surveying apparatus. (3) Dental maps in three dimensions. (4) Effects of the "overbite" and "compensating curve" on occlusion. I would also refer to a paper presented at the Panama-Pacific Dental Congress and published in the proceedings, entitled "An instrument for Mapping the Denture," by Frederick Lester Stanton and Rudolph Hanau, M.E.

By means of bisecting lines skulls at Washington were surveyed and data collected in regard to the form and dimensions of the normal arch in races with widely differing arches and skull formations. This yielded results. When the data were examined it was found that in normal skulls there was a small variation of the width of the arch relative to the variation in its length. A line was drawn across the arch at the buccal groove of the first molar. The width of.

the arch was measured on this line from a point in line with the summit of the buccal cusps. The height of the dental arch was measured from this width line by a perpendicular to the central incisors. The variation in the width of a dental arch is only 18 per cent. The narrowest arch was 52 mm., and the widest 62 mm.; variation in height, 50 per cent. Shortest arch, 21 mm., longest 34 mm. Or, expressing it differently, in the placement of an upper first molar we have a range of only 5 mm., but in choosing the position of incisors (centrals) the range of variation is 13 mm.

The next step was, by engineering methods, to predetermine the form and dimensions of the arch for any given set of teeth.

These slides [exhibiting] illustrate—(1) A drawing-board method of trial devised by Mr. Hanau—a method which consists of selecting various curves and laying off the mesio-distal diameters of the teeth until a curve is found that would permit of occlusion (as described in full in the Panama-Pacific Congress paper referred to). (?) A method of determining occlusion by means of an engineering instrument, the "Occlusograph," designed by Gilbert D. Fish, C.E. (as described and illustrated in a paper entitled "Technology in Orthodontia," by G. D. Fish, *Internat. Journ. of Orthodontia*, June 1917).

By the use of these maps it is possible to select an appliance to accomplish the desired movements of teeth in accordance with the principles governing analytical mechanics.

These slides [exhibiting] illustrate "models of malocclusion," with maps of the models; predetermined occlusion, appliances used to move the teeth, models, and maps showing results of treatment. (This phase of the work was illustrated in a series of papers published in the *Dental Digest*, February to September 1917, entitled "Science vs. Empiricism," by F. L. Stanton.)

Angle, and the teachers who follow his text, attempt to describe the positions of teeth by referring them to the line of occlusion, ignoring the true scientific

method of locating bodies in space. "The position of a tooth in occlusion or malocclusion may be accurately stated by giving its relation to the three axes or planes assumed."* The classification of malocclusion by Angle rests on an assumption that is untrue, hence it is a dangerous teaching formula, often leading to a wrong diagnosis and a faulty plan of treatment. Postgraduate and undergraduate schools are still using and teaching the use of the "Hawley arch." This plan should be abandoned, as it rests on the false assumption of the Bonwill triangle, making all dental arches of the same form.

In the September 1916 *DENTAL COSMOS*, Angle describes a new form of orthodontic appliance. In the case illustrated there is a wrong principle of treatment; the indicated attachments should not be made to the front teeth at the beginning of the treatment. The dental arch, like any other arch, must be built from its base first. As the bicuspid are the teeth most at fault, these must (with the molars) first be placed before any attempt is made to adjust the front teeth. In a paper published in the September 1917 *DENTAL COSMOS*, G. D. Fish, C.E., states: "Mechanical simplicity and definiteness are not to be found in such a device as the Angle ribbon arch. Ask any engineer to analyze the forces exerted upon the teeth by such an appliance, and he will tell you that the factors are too uncertain."

Engineering principles must be investigated by our teachers, and preparation made in our dental schools to inform the students on this subject. New appliances in orthodontia and dentistry should be submitted to technical men before being used in the human mouth.

28 W. THIRTY-NINTH ST.

DISCUSSION.

Dr. F. A. Delabarre, Boston, Mass. I have studied Dr. Stanton's progress in the development of this application of engineering principles to orthodontia for

* "An Instrument for Mapping the Denture," *Proc. Panama-Pacific Dental Congress.*

a long time. I have spent serious thought and a great deal of time on the proposition. I feel that I cannot pay a sufficient tribute to him in commendation of his effort along this line of thought—an effort that, it seems to me, is bound to bring a most definite and positive result in orthodontia.

You who have approached this subject for the first time, who have seen the clinical demonstration, watched these charts on the screen and listened to their explanation, unless you are particularly acute mentally, must be more or less confused. I confess that I am. I am not technically educated along engineering lines, but I think if we put aside for the moment all thought of the intricacies of this thing, and ask the fundamental question, "Is engineering applicable to this particular problem?" our answer must be, "Yes." The value of the results we get must depend upon the proper working out of these principles. Dr. Stanton has the idea and ideals and the "vision" of the genius to approach a proposition of this kind and devote to it all the energy with which he is endowed, and I think all of us who are not similarly endowed should stand behind him and give him what encouragement we can. He has made the assertion that orthodontia of the past and of the present is absolutely without any scientific foundation, and I believe this is true. When it has succeeded in the past it has been a matter of chance, very largely. I do not want to flatter Dr. Stanton by saying that he has attained to ultimate perfection, because I do not think that he has. He is, however, on the high-road to it. There are many things I want to see. I want to see normal occlusion adequately and scientifically defined, and defined to the extent that will allow us to analyze any case of malocclusion and say positively and scientifically, without the fear of dispute, that it is a malocclusion of such-and-such a degree, or to take a case and say that it is absolutely a case of normal occlusion. The orthodontist has not been able to do this. He has only been able to give you his opinion. The more

intensive study and the longer time that our specialists in orthodontia give to this field only serve to develop our ignorance along this line.

Speaking to you as dentists, and not as orthodontists, I want to say that I should like you to get this one practical point that has been driven home to me most conclusively this morning—something that I have believed in for a long time, but which the profession has not yet adopted in its dealings with patients—that is, if you are going to deal with a malocclusion, you must do it early in life, before the malocclusion has developed into any of those complicated forms shown this morning. The moment you see, at the age of five or six years, a child whose teeth and jaws have started toward malocclusion, even if you can detect only the slightest tendency, that is the time when corrective measures should be instituted. From my contact with the profession I know that its members have not yet accepted the essential truth of the necessity for the correction of malocclusion by early treatment. It is the only logical method of procedure. If you find that a builder is not following the plans of the architect, do you wait until the building is finished before you tell him to stop, and do the work right? No; you stop him immediately. Now, nature, in building the individual, is not developing the child correctly according to the plans and specifications, due to some internal or external force, and the reasonable thing to do to stop that variation, that maldevelopment, is to step in and aid nature to develop the parts normally.

The whole question cannot be considered merely from a mechanical standpoint. Dr. Wheeler told us this morning that our profession is deficient in the application of knowledge to the problems of dentistry dealing with living tissues. This is also true of orthodontia. It is not purely a mechanical, but a biological question as well. The forces of life, the forces that go to the building up of tissue, are all involved, and the orthodontist who is a mechanical man alone is not fulfilling his whole duty.

I want to congratulate the profession on having a man in it who can attack a question of this kind and bring it to the point where he can handle the mechanical aspects of the problem in such a manner as Dr. Stanton has. Our profession is growing very rapidly, and I am glad that the specialty of orthodontia is not lagging behind. I feel sure that the further development of this idea that Dr. Stanton has brought out is going to mean the solution of the orthodontic problem.

Dr. Ira B. Stilson, Providence, R. I. An instrument has been presented to us that is so highly scientific, so accurate in its construction and in its operation, that it commands the admiration of everyone who sees it. We often make the remark that we cannot achieve perfection, but there can be no harm in attempting perfection, and coming as near as possible to it. Dr. Stanton has shown us here what we might call a perfect method for predetermining the shapes of the dental arches that come into our hands for correction. Those of us who have studied with and under Dr. Stanton have noted in amazement, during the last few years, his progress, as he has successively presented the different steps in the development of this advanced theory of the treatment of malocclusion. I feel that I am inadequate to discuss the paper for the reason that I have not sufficient mechanical ingenuity to comprehend Dr. Stanton's mechanism, and I believe I am not alone, because, as we have talked the matter over among ourselves at our meetings, many of us have felt that the mechanics of the thing was beyond our grasp. That, however, certainly does not condemn it.

There is much besides mechanics, however, to be taken into consideration in the treatment of orthodontic cases. We have all treated cases of malocclusion by guesswork or otherwise. We have sometimes succeeded in establishing what, to our minds, was a pretty fair degree of occlusion. We have made models of some of our finished cases, perhaps in nearly as good position as Dr. Stanton's in some instances, and have

shown them with considerable pride. At the end of two or three years, however, to our chagrin, we did not have normal occlusion as we had it in the case when first finished. Something else than malocclusion had been active there—for that we had corrected. We have had cases, on the other hand, in which we were not able to establish normal occlusion quite to our satisfaction. Perhaps we did not reach the exact arch form that we should have reached, but a year or so later, to our gratification, we found that the case had improved after leaving our hands, showing evidence of the forces of occlusion. We know that these forces are present and we endeavor to work in harmony with them, but these forces work differently in different cases. Sometimes the particular forces of occlusion that we are trying to enlist do not seem to act in the way that they should. They operate not simply as forces of occlusion *per se*, but they operate to some remote point—perhaps at the apices of the roots, or in the bony structure above or below the apices. For some reason, a given force will operate one way in one case, and another way in another case.

These are the problems that seem to give the orthodontist the greatest difficulty, and they are problems in which I cannot see that the mechanical phase of the question is going to be a help to us. I do not say that it will be a hindrance, however. There can be no harm in predetermining the form which the arch should take, but it is not always the one in which it will remain, I believe. I think one of the reasons why we have difficulty in maintaining occlusions for the subsequent two or three years as we have them when the work is finished is to be found in a lack of development during the growing period of the child. The forces have become, as we may say, habituated to an action that they acquire during the stage of malocclusion, and we are not able to change these forces—these habits of action. I believe, therefore, that we can seldom get a perfect function of all the forces of occlusion in cases in which the malocclusion has been extensive, and has been continued until almost the full

growth of the child. For that reason I wish, with Dr. Stanton and Dr. Delabarre, to make a plea to you men who are doing orthodontia, for the early treatment of cases of malocclusion. If there is malocclusion at four or five years, there is no reason why treatment should not be begun then. Dr. Delabarre said if the spaces do not begin to form before the age of six, he would start treatment. They begin normally long before six. The child's arch is formed at the age of two and a half years, and often children come to us at the age of six with an arch no larger than it was at the age of two and a half years. The child is larger, but the arches are not. There has been an entire arrest in the development of the bone in which the teeth are enveloped, the foundation on which the teeth must rest. I put in expansion arches at the age of four years, if I see no spaces beginning to form between the incisor teeth. I shall certainly do this in the case of my own children, if I find that at the age of four years nature has not begun to form the spaces that it should.

I have the greatest respect for the work of Dr. Stanton, as all must have, even those of us who are not able to comprehend the beauty and efficiency of his mechanics. There is one phase of the treatment, however, as shown by Dr. Stanton, that almost appals me. If I should secure such extensive movement in so short a time as he has indicated, I would be alarmed. In the last few years I believe that the trend of orthodontic treatment has been toward a slower tooth movement, so that we may have what is termed physiologic tooth movement, a full, well-formed bony bed for the teeth to rest on in all stages of their movement.

Dr. C. Frank Bliven, Worcester, Mass. If Dr. Stanton's presence has been of any value to our association and to humanity, I am certainly very thankful.

If his demonstration of yesterday and his remarks of today are of no value, I am the guilty one, as I am responsible for his presence. I persuaded him to come because of my absolute belief that

he has discovered the real fundamental principle of correcting abnormal occlusions.

These abnormal conditions are the result of insufficient nutrition, prenatal and present; not only this undeveloped arch, but the entire system depends on the law of nutrition. How often do we see a physically perfect man? I do not believe Dr. Wheeler has found many among those he is called upon to examine. The nutritional system is much the same as the water supply of a city. If, from any cause, the reservoir or the feed pipe from the reservoir becomes obstructed, that part of the community to which that pipe leads cannot receive its supply of water. So in the human system, if there is lack of nutrition owing to prenatal and present conditions, the supply is inadequate to produce normal growth.

Working with Mr. Perdy, the inventor of the shredded wheat biscuit, a number of years ago, it was my pleasure to examine the mouths of many nationalities throughout the city. There were few who had perfect arches or teeth. Among the children examined I found only one in whom the teeth were in perfect occlusion. In one Syrian family examined, the mother had lost two teeth and had at that time six cavities. In all of these cavities the decay was arrested. The breaking-down process had ceased in her mouth. She had two sisters and a cousin whose ages ranged from twenty to twenty-three, and all these girls had perfect teeth, with no cavities. I asked what care they gave their teeth. The only one who spoke English fluently said they did not use toothbrushes, as it injured the gums. They used only a flannel cloth on their teeth.

In another Syrian family there were four grown girls and a mother. In every mouth I found perfect teeth; no cavities and no evidence of any attempt at cleanliness other than that which nature provides. I tried to analyze the physical and mental differences between these Syrian families and those of other nationalities in relation to the teeth, and it resolved itself into the question of nutri-

tion and the mental conditions which arrest or accelerate nutrition.

It seems to me that one of the great advantages of Dr. Stanton's system is the wonderful assistance it will be to dentists in small communities, thus benefiting the future race of the communities. A dentist in a town of five, six, or seven thousand inhabitants has no opportunity to give orthodontic treatment to any except the few wealthy persons in that community; the rest must go without.

Dr. Stanton has discovered a method which will enable any intelligent dentist in a small town to take orthodontic cases and carry them to a successful termination. These results have only rarely been accomplished among the leading orthodontists. I have had my own troubles, and I believe in the future Dr. Stanton will correct them for me. The younger men will become students of Dr. Stanton's work, and this will introduce it into all communities, thereby benefiting the entire dental profession and eliminating the failures of the past.

After the teeth have been placed in normal occlusion by Dr. Stanton's method, will they retain their position, without attention to the systemic nutrition? This is an important consideration, for should the teeth return to their former position after having been placed in normal occlusion by the essayist's scientific method, orthodontic interference had better be dispensed with, and scientifically constructed artificial substitutes supplied where sufficient masticating surfaces are lacking.

It is my belief that, even with insufficient nutrition, Dr. Stanton's system will make it possible to vastly improve the coming generation, and simplify orthodontic work for the dental profession.

Dr. Stanton (closing the discussion). I have never been more embarrassed in my life. This is the first time that I have read a paper on dental engineering that did not provoke a controversy. The next time I read a paper I am going to ask the president of the society to bar the word biology from the discussion. I bring before you a definite proposition,

saying that dentistry is founded on biology and mechanics. Let us dismiss biology, as I did not come to discuss it. Dentists are not trained in mechanics. Dental teachers are not able to solve the simplest problem in analytical mechanics. The simplest problems in the mechanics of the dental arch are not understood. Mechanics, as taught in the technical schools, should be taught in our dental schools.

Dr. Stilson pays me a few compliments, and then slides off into biology. My paper today has nothing to do with biology. If you want to establish normal occlusion, I can plot occlusion on the drawing board, as an engineer handles his problems. By making maps of the malocclusion and occlusion the relative movement of all teeth can be determined. This process is a kinematic problem, with which the biologic problem should not be confounded. Good mechanics cannot be properly applied to straightening teeth without due regard for and knowledge of biology.

If arch determination is a kinematic problem and if appliance designing is a dynamic problem, it behooves us as a profession to inform ourselves in this branch of science—mechanics. Mechanics should be taught in every dental school. Not only orthodontia, but all branches of dentistry would be benefited by a more extended familiarity with the science of mechanics.

Dr. Stilson. If Dr. Stanton wishes to have a discussion on mechanics, he should read his paper before a society of engineers. We must speak from the knowledge we possess.

Dr. N. B. Nesbitt, Boston, Mass. As a guest of this society and a man known as a mechanical dentist, and one exceedingly proud of the title, I want to say that Dr. Stanton is the first man that I have heard get up and attack the problem from a scientific point of view. He has approached the subject in the proper way, by going to engineers for the data he wished to get for his results. If we are not mechanical men, we should not undertake any problems of either orthodontia or prosthetic work. I want to

thank Dr. Stanton again for coming before us as mechanical men.

The President appointed the following as members of the committee to formulate plans for carrying out the recommendations in the President's Address, as approved by the Committee on President's Address in their report: Dr. W. R. Pond, Rutland, Vt.; Dr. Charles McManus, Hartford, Conn.; Dr. Thomas J. Barrett, Worcester, Mass.; Dr. A. J. Sawyer, Manchester, N. H., and Dr. Wm. S. Greene, Newport, R. I.

The report of the Auditing Committee was then read by Dr. T. J. BARRETT.

On motion the report was accepted and placed on file.

Dr. Bush and Dr. Holmes were asked by Dr. Manson to escort Dr. Stilson, the

newly-elected president, to the chair. Dr. Manson, with a few appropriate words, turned over the gavel of office to Dr. Stilson, who replied as follows:

Dr. STILSON. I do not overlook the honor that has been conferred upon me by the association, but the emotion which moves me today is not a feeling of honor, but one of responsibility. This is not, and cannot be, a one-man organization, and I plead for the support which my predecessor has asked you to give me. I think that the meeting this year has been the best meeting that this society has given its members in a number of years. I ask your support and co-operation in order to make the next as good or better. I thank you.

There being no further business before the society, Dr. Stilson declared the meeting adjourned.

THE DENTAL COSMOS

A MONTHLY RECORD OF DENTAL SCIENCE.

Devoted to the Interests of the Profession.

EDWARD C. KIRK, D.D.S., Sc.D., LL.D., *Editor.*

PHILADELPHIA, APRIL 1918.

EDITORIAL DEPARTMENT

Pending Navy Dental Legislation.

IN our previous issue we printed the text of a bill, S. 3386, introduced by Senator Lodge, the purpose of which is to give to the Navy Dental Surgeons Corps a status corresponding to that accorded to the Army Dental Surgeons Corps by the act of October 6, 1917. We understand that the Navy Department is willing to accept the principle involved—namely, to recognize the equality of professional status of the dental surgeon within his corps with that of the army surgeon within the Medical corps. In connection with the Lodge bill as published in our March issue we appended the following note: “We are informed that the above bill in its present form does not fully meet the requirements of the Navy Department, and that other legislation involving the principle of

equality of status for the Medical and Dental corps is under consideration."

Subsequent to the above writing, *i.e.* on February 5, 1918, Senator Tillman introduced a bill, S. 3749, "To Reorganize the Dental Corps of the Navy, and for Other Purposes."* This bill is understood to embody the views of the Bureau of Navigation of the Navy Department regarding the application of the principle of equality of rank, as to the medical and dental services respectively, in the navy. Both bills are for the present on file with the Senate Committee on Naval Affairs, to which they were referred after having been twice read in the Senate.

There are certain matters underlying this legislative effort that call for serious consideration. Nearly sixty years ago the preliminary steps were taken to secure to those in the defensive service of our nation the benefits of systematic dental and oral treatment. The movement was initiated at a meeting of the Western Dental Society held in Quincy, Ill., when favorable action was taken on a resolution presented by the late Dr. H. J. McKellops of St. Louis, providing for the creation of a committee to take charge of the matter of securing national legislation creating a dental service in connection with the army. As the resolution is of historic importance we here reproduce it from the report in the *Dental News-Letter* for October 1858, page 37:

Dr. McKELLOPS offered the following preamble and resolution:

Whereas, Owing to the great inconvenience of the officers and soldiers in procuring competent dentists, when necessarily required, and knowing the difficulty in which they are placed, being stationed at distant posts where it is absolutely impracticable for a regular practitioner of dentistry to visit them; therefore

RESOLVED, That this society appoint a committee of five, for the purpose of memorializing Congress on the necessity of dentists to be attached to the regular army, and that we recommend the same to the consideration of the American Dental Convention and ask their co-operation with us.

The committee appointed pursuant to the resolution consisted of Drs. McKellops, Spalding, Forbes, Branch, and Lewis, and the president of the society, Dr. W. W. Allport, who was subsequently added by vote of the society. No tangible result other than the development of a favorable professional attitude of mind toward

* This bill, which was also introduced by Mr. Dyer in the House of Representatives as H. R. 10724, will be found at page 365 of our present issue.

the object in view flowed from the above-quoted resolution until 1900, when the Otey bill providing for the creation of an army dental service on a contract basis became law. It took over forty years to even partially realize in a practical way the purpose defined in the McKellops resolution.

With justifiable dissatisfaction as to the undignified and at the same time impotent position given to the dental surgeon in the army service under the Otey law, strenuous efforts were made to place the corps upon a commissioned basis, culminating in the passage of the Army General Appropriation Bill H. R. 31237 on March 3, 1911, containing the clause which placed the Dental Surgeons Corps upon a commissioned basis, but with rank, pay, and allowances inferior to those accorded the medical corps. On October 6, 1917, this distinction was wiped out by Congressional action, and the dental corps was given legal status equal to that of all other branches of the medical service. As already stated, it has taken nearly sixty years of effort and agitation to reach the goal anticipated by the McKellops resolution.

Three factors, in our opinion, have been prominently active as obstacles to the earlier achievement of the ends now attained. First: Diversity of opinion within the dental profession as to what ought to be achieved in legalizing dental service in the army and navy. Second: Opposition by the medical profession toward any effort to place dentists on an equal status with physicians and surgeons in the national service; and Third: The baleful influence of a minor self-seeking group who in the effort to continually safeguard their own selfish ends have opposed and from time to time have defeated, by creating discord and inharmony of action, legislation conceived and framed for the good of the service and the good of the dental profession.

This element has served to impress the Congress or its committees with the belief that the dental profession did not really know what it wanted—that there was solidarity neither of mind nor of action with regard to national dental legislation; and so the matter dragged its weary and checkered course through more than half a century before a successful result was achieved. No question affecting the status of dentistry is of more fundamental importance than the light in which its activities are viewed by our national Government. The definition of professional status of

the Army Dental Surgeons Corps embodied in the law of October 6, 1917, is an official recognition of the professional position for which its votaries have contended since the birth of dentistry as a profession; but until the same definition and status is accorded by law to the navy dental service the achievement is but half attained, and the vexed question of professional recognition for dentistry will remain an open one.

Congress will undoubtedly do, in principle and in effect, for the navy what it has already done for the army dental service; but its effort in that direction must not be hampered by ignorance, disharmony, or self-serving ambitions upon the part of any who would impress that influence on the framing and promotion of the necessary legislation in behalf of the dental profession. We should have had a commissioned dental corps a half-century ago if the dental profession could have presented a solid front to Congress on this question and the superserviceable and self-seeking meddler had been eliminated. Let us profit by experience. The Tillman bill is a fair statement of the attitude of the Navy Department, and is in general representative of the view of the Navy Dental Surgeons Corps. If it is to be modified in the Senate Committee on Naval Affairs, as doubtless it may be before its final passage, let the required changes be made by those who are looking to the conservation of the higher ideal of increasing the efficiency of the service conformably with the proper dignity of the dental profession and the views of those who are sufficiently familiar with the whole situation to be able to deal with it intelligently and effectively.

Above all, a determined resistance should be made to the activities of the intermeddling self-seeker whose only interest is the promotion of his own selfish objects. In these days of social regeneration when the world war is revealing a new and we believe higher meaning for the life activities of mankind, there should be no place for the individual whose primary consideration is himself. Where selfishness has interposed its influence we have lost, and where an altruistic spirit of service has dominated we have won in this national legislative effort. The record is clear; let us not repeat our mistakes.

Incidental to the proposed navy dental legislation it is pertinent to call attention to the fact that by a decision of the Judge Advocate-general the provisions of the act of October 6th reorgan-

izing the Army Dental Corps are applicable to the Army Dental Reserve Corps as well. Following out the same principle, analogous provision should be made with reference to increases in rank, etc., in the Naval Dental Reserve Corps, and we hope that this point may receive the serious consideration of the several legislative committees who will have the matter in charge. There is no proper reason why effective legislation according a status to the Navy Dental Corps, both regular and Reserve, on a parity with that accorded the corresponding Army Dental Corps, should not be passed at this session of Congress. Now is the accepted time, and the parties in interest should act vigorously as well as intelligently.

"l'Aide Confraternelle" Honor Roll.

IN response to our appeal in the January issue we have received the following contributions to "l'Aide Confraternelle":

| | |
|-----------------------------------------------------|----------|
| Reading Dental Society, Reading, Pa. | \$25.00 |
| Dr. H. H. Wilson, Phoenix, Ariz. | 10.00 |
| Dr. Morris Mestel, New York, N. Y. | 5.00 |
| Dr. N. P. MacDermid, Charleston, W. Va. | 10.00 |
| Dr. Wm. C. Fisher, New York, N. Y. | 10.00 |
| Dr. J. H. Oliver, Philadelphia, Pa. | 10.00 |
| Dr. Harry Bear, Richmond, Va. | 2.00 |
| Dr. B. B. Detwiler, Herndon, Va. | 1.00 |
| Dr. Herbert L. Wheeler, New York, N. Y. | 50.00 |
| Dr. Jules J. Sarrazin, New Orleans, La. | 5.00 |
| Dr. L. P. Bethel, Columbus, Ohio | 10.00 |
| Bureau of Fourth International Dental Congress | 82.50 |
| Dr. E. C. Kirk, Philadelphia, Pa. | 25.00 |
| | \$245.50 |
| <i>Previously received.</i> | |
| Dr. J. W. Jungman, Cleveland, Ohio | 5.00 |
| Total | \$250.50 |

We hope that this modest beginning may presage a more liberal expression of sympathy on the part of the dental profession of America for their destitute and suffering transatlantic colleagues. All amounts received will be promptly forwarded and acknowledged in succeeding issues. Your prompt and liberal contribution is solicited.

BIBLIOGRAPHICAL

AMERICAN ILLUSTRATED MEDICAL DICTIONARY. A New and Complete Dictionary of Terms Employed in Medicine, Surgery, Dentistry, Pharmacy, Chemistry, Veterinary Science, Nursing, Biology, and the kindred branches; with new and elaborate Tables. Ninth Edition, revised and enlarged. Edited by W. A. NEWMAN DORLAND, M.D. Large octavo of 1179 pages, with 331 illustrations, 119 in colors. Containing over 2000 new terms. Philadelphia and London: W. B. Saunders Company, 1917. Flexible leather, \$5.00 net; thumb index, \$5.50 net.

The construction of a dictionary calculated to fairly cover the vast field of modern medical terminology is an arduous task whose faithful accomplishment is worthy of grateful acknowledgment on the part of those whose daily queries it is found to solve; and the present-day lexicographer who in successive editions has to live up to an established reputation for "keeping abreast" has no sinecure. New ideas are ever springing up and new words describing them demand recognition. In the present edition of the American Illustrated Medical Dictionary it is understood that about 2000 entries make their bow to its professional *clientèle*.

Of itself, the demand for a ninth edition of a work emanating from the literary travail of Dr. W. A. Dorland and his associates and whose material soma

pany is a guarantee of excellence, which is confirmed by the general evidences of advancement in the path along which these sponsors have hitherto brought this important work.

A number of the newer terms have arisen in the course of the professional activities called forth by the present international conflict. Nor could it be otherwise in a faithful record in these stirring days, owing to the many beneficent advances in diagnostic and medicinal means and methods that are ever cropping forth, and the marvelous surgical improvements to which recourse is now available, and when even new pathologic entities are making their appearance—all of which must be given a local habitation and a name in an up-to-date reference book. And we find here, *e.g.*, such entries as ambrine, chlorazene, flavine, tryptaflavine, javellization, Lacleinché-Vallée serum; such pathological designations as "trench back," "trench foot," "trench fever," etc., and a score, perhaps, of "war abbreviations," as P. U. O., an English designation for the fever just named, the initials representing "Pyrexia of Unknown Origin." In which last phrase, by the way, occurs one of the extremely few typographic slips, giving the word as Pyreria. On page 863 we find an *a* for the middle vowel in a mention of the city of the famous shrine of the many-breasted image that "fell down from Jupiter," whose claims when challenged the enthusiastic citizens overwhelmingly established by making the amphitheater ring for 120 minutes

by the clepsydra with "Great is Diana of the Ephesians!"

In the war abbreviations there is doubtless a present utilitarian value; in less hasty times, however, on the hoped-for re-establishment of a live-and-let-live international philosophy they may well be allowed to fall into "innocuous desuetude." With the necessarily multiplying abbreviations in the sciences, it would seem that the ministrants of healing need not add to them, but so far as possible abide content with those called for in prescription writing and other established uses. There is much liability to ambiguity, and this may be fraught with danger to life.

Of handsome exterior, with its red leather flexible covers, this "large 8vo" book maintains a high typographical ideal, exhibiting experienced judgment and excellent workmanship. The body type is clear, notwithstanding its necessarily small size; the heavier type of the overhanging entries is harmonious with it, and the Greek derivations are given in an admirable Greek face, neither too bold nor too slim, and well adapted to accompany the English type. Judicious selection is evident in each feature, making the page inviting to the discerning eye; and thin but opaque paper combines with first-class presswork to give a clear impression and uniform "color" from beginning to end.

Speaking now of other general impressions, and first of the illustrations, it is welcome when referring, say, to the anatomic tabulations of arteries, veins, muscles or nerves, to find these pictured in colors on the pages immediately facing their mention. The illustrative material has been subject to considerable additions; there are, in fact, as many as 115 colored illustrations in this edition, and

of those in black and white over 300. As to tables, it would seem that about everything suited to tabular presentation is found here, including those of the exanthemata, of signs and symptoms, of serums, tests, reactions, staining and fixing methods; of operations; the various "procedures" known as such are given, the special technique being indicated. The posologic and therapeutic table at the end is a full one, occupying 50 pages. The brief biographies of the men whose names are specially connected with diseases, or methods of treatment, or operations, constitute an invaluable feature.

While for the province of dentistry a special wordbook is called for—and there are parturient symptoms of new dental nomenclature even at this moment—yet the dentist, it goes without saying, almost as much as the physician, must be familiar with innumerable matters that are constituents of this medical dictionary, while the feature of its recognition of dental terms has already, in the eighth edition, been commended in the *DENTAL COSMOS*. It may, however, be remarked in connection with the word *Tooth* (the words *Tooth* and *Teeth* take up about three-quarters of a page), that, after mention of the "root or fang," the latter word is unfortunately chosen in each of several subsequent mentions of the root. This is a blemish; the dental profession has abolished the "fang." Uncorrected, this is liable to cast an unjust reflection upon the other dental entries.

The *DENTAL COSMOS* has from time to time commended what is known as the "dictionary habit," and its application to the work before us could not but prove most fruitful of real interest and abundant profit. Whether this book be taken up from time to time with the purpose of recalling partly forgotten knowledge,

and of adding thereto, or to make references when perusing professional literature or contributing to it, or whether, again, in the exigencies of practice recourse may be had to its valuable epitomes of symptoms and methods—for these may be recalled instantly here, even

the quite recent ones—the practitioner of healing is furnished with a treasury of information for his own advancement in knowledge, for immediate aid and counsel in emergencies, and for the promotion in various ways of his usefulness to his patients.

REVIEW OF CURRENT DENTAL LITERATURE

[*British Medical Journal*, London, January 12, 1918.]

Solvents for Dichloramine-T. By H. D. DAKIN AND E. K. DUNHAM.

Dichloramine-T is readily soluble in most organic solvents, with the exception of the paraffin hydrocarbons. The majority of these solutions are of no value for practical purposes, since the dichloramine-T contained in them is rapidly decomposed. Among the few solvents which give reasonably stable solutions many had to be rejected on account of their proving too irritating, so that it will be realized that the selection of a suitable solvent for dichloramine-T is a somewhat difficult problem.

The authors undertook a systematic survey of other possible solvents with the object of finding a cheaper and blander substitute for eucalyptol (the one hitherto most generally employed). This aim is believed to have been accomplished, at least in part.

It appeared, from extensive experiments, improbable that solvents containing oxygen were likely to prove successful, since they usually abstract chlorine from the dichloramine-T too readily. The choice then practically resolved itself into halogen derivatives of other hydrocarbons of the aromatic, aliphatic, and other series.

The authors turned, after experimental elimination of other possibilities, to the chlorine derivatives of the higher aliphatic hydrocarbons.

It was found that paraffin wax could be readily chlorinated under easily regulated conditions. The product when prepared as described below was an extremely bland, rather viscous oil, which readily dissolves dichloramine-T. The solution so prepared was stable over long periods, if kept under suitable conditions. The authors have provisionally chosen the name of "chlorosane," for this solvent, since the systematic names of most of the hydrocarbons in paraffin wax end with the suffix "cosane."

Chlorosane is prepared as follows: Paraffin wax, of a melting-point at 50° C. or higher, is placed in round-bottomed flasks and heated to about 120° C. Two flasks connected in series, each containing half a kilogram of the wax, may be conveniently used. A rapid current of chlorine from a cylinder of liquefied gas is then passed through the molten wax in the flasks, each of which is provided with a thermometer and the necessary glass tubes. The temperature should be controlled within the limits of 125° to 140° C. The first flask, in which the reaction is the more vigorous, will require but little heating. Chlorination is continued until the contents of the flasks have increased in weight 45 to 65 per cent. of the weight of the wax taken. It will be found convenient to complete the chlorination of the first flask and then remove it, and transfer the second to its place, putting a fresh flask of paraffin wax after it. In order to avoid undue discoloration of the product, a minimum amount of rubber tubing should be used

for passing the gases, and the ends of the delivery tubes are preferably blown into bulbs provided with a number of fine orifices to promote good contact between gas and oil. Hydrochloric acid is freely evolved during the reaction. After the requisite amount of chlorine has been absorbed, the oil, while still warm, is shaken vigorously with 5 per cent. of its weight of dry sodium carbonate, and then filtered through a dry fluted paper. The clear oil, which has a light yellow or sherry color, and is slightly heavier than water, is then ready for use. It possesses a viscosity intermediate between that of olive oil and castor oil, has almost no odor, and is perfectly bland when sprayed up the nose or placed on skin or wounds.

The materials necessary for making this new solvent are all easily available at very small cost. It has no appreciable antiseptic action. At room temperature it can dissolve from 8.5 to 10 per cent. dichloramine-T. For wound treatment a 7.5 to 8 per cent. solution is strong enough. After heating the solvent, "chlorosane," to 75° or 80° C., it will easily dissolve the necessary quantity of dichloramine-T. If necessary, filter, although with pure materials this is not required. The clear solution should be at once stored in small amber corked bottles, and not exposed to unnecessary heat.

Under ordinary conditions solutions which are protected from light by amber bottles and from contact with water or excessive heat may safely be used for two months, or possibly longer. The clinical results of dichloramine-T in this new solvent are similar to those already recorded by Lee, Sweet, and others.

[*New York Medical Journal*, January 12, 1918.]

Oral Sepsis and the Anemias. BY M. L. GRAVES.

Anemia constitutes but one of the numerous clinical manifestations of sepsis or infection, whether it originates in the mouth or elsewhere. The author agrees with the belief of Wm. Hunter that pernicious or infective anemia should be ascribed to mouth infection.

One concrete case under Graves' personal observation illustrates this. Rigid examination failed to reveal any focus of infection save the mouth, which showed a bad glossitis

and pyorrheal abscesses about all the few remaining teeth. The administration of 5200 cc. of blood by citrate infusion at intervals, the use of salvarsan intravenously, the administration of HCl, and good food and rest, resulted in an only very temporary improvement. However, the removal of all the infected teeth permitted a rapid and marked improvement. The patient returned to a laborious occupation with the appearance of health and a blood exhibit approximating normal.

Salivary Fistulæ. BY L. DIEULAFÉ. (August.)

Two Cases of Fistula from the Parotid Gland, Cured by Resection of the Auriculo-Temporal Nerve. BY DEUPÈS. (July.)

The article by Dieulafé is the more comprehensive of the two. The increased incidence of facial wounds in modern warfare increases the frequency of salivary fistulæ. In civil practice and also in war surgery the two varieties which vastly predominate are parenchymatous fistulæ of the parotid and fistule of Stenson's duct. For a fistula of the parenchyma of the parotid, at one time or another the following means have been advocated:

(1) Compression and excision of the fistulous tract. These have proved themselves insufficient.

(2) Cauterization, either with silver nitrate or thermo-cautery. This has given some good results. In mild cases Dieulafé always advises to commence treatment with one or the other of these methods. They are particularly adapted to fistulæ sequent to intraglandular suppurations.

(3) Injections of oil into the fistulous tract. In two cases where this was tried by Dieulafé the result was ephemeral.

(4) Creation of an intrabuccal opening by transfixation. The author tried this method in three cases, in one of which it did not succeed.

(5) Resection of the auriculo-temporal nerve. On account of the complexity of the innervation of the parotid gland the author was not too sanguine of an absolute drying-up of the parotid secretion by resection alone

of this nerve. For this operation local anesthesia should be reserved for those cases where there is no inflammation or cicatricial tissues in the region where the nerve is to be sought. The secretion never stops immediately after the operation. Dieulafé practiced this method three times in healthy surroundings and twice in cicatrices. In all five cases the secretion was prolonged after the operation, then it disappeared. In two cases it was necessary, in order to complete a cure, to resort to cauterization, which had previously by itself failed. When everything is taken into consideration this operation leads to the desired therapeutic success.

Deupès has confined his attention in his report exclusively to this method of treatment, namely, resection of the auriculo-temporal nerve. In his experience salivary fistulae, together with facial paralysis, are very frequent sequelae to the cicatrization of extensive regional lacerations. His two cases are those of fistulae from the parotid parenchyma. He summarizes his operative procedures as follows:

(1) Local anesthesia under novocain-adrenalin.

(2) Vertical incision, about 3 cm. long, half above and half below the zygomatic arch.

(3) Search for the nerve. The pulsations of the temporal artery have not served as a landmark. It was necessary to seek under the upper part of the incision for a peripheral filament of the nerve, and to follow this to the trunk.

(4) Dissection of the nerve in the sheath to the lower part of the incision, that is, to the glandular tissue.

(5) Gentle traction on the nerve with a hemostat, so as to obtain as great a length as possible until rupture. This step of the operation was always quite painful.

(6) Reunion of the cutaneous borders with the clasps of Michel.

On the next day, on removing the dressings, there was proof that this operation, benign, without blood, and rapid, had perfectly succeeded.

The remainder of Dieulafé's paper is concerned with the fistulae of Stenson's duct. Among the war-wounded it is possible to recognize divers pathogenic groups: (1) A very limited traumatic injury to the cheek, by a shell splinter, directly involving Stenson's

duct, and creating a fistula as a result of a lateral section of this duct; (2) great lacerations of the cheek by shell splinters, followed by retractile cicatrices encircling the duct, obliterating its normal orifice and leaving open toward the skin the wound, which involved the duct; (3) traumatism, again by shell splinters having involved the bones and soft parts, resulting in inflammatory phenomena which open, abscess, and make a fistula out of Stenson's duct. The second variety is the most frequent; each of the others has been observed by Dieulafé but a single time.

In spite of the frequency of facial lesions among the war-wounded, of their seriousness, and of the vast lacerations which they produce, the author has gained the impression that the fistula of Stenson's duct is a rare complication. The following methods of treatment are mentioned, and some of them are briefly outlined: Compression of the gland or the duct, the injection of substances tending to promote atrophy, absolute immobilization of the jaws, cauterizations of the fistulous tracts (in one case by this method Dieulafé obtained a cure; the wound was completely limited to the buccinator region, and bordered directly upon the canal), simple occlusion of the fistula, suture of the fistula, suture of the two ends of the duct together, re-establishment of the permeability of the anterior (distal) end of the canal, the creation of an artificial passage toward the mouth (this method by transfixation has appeared to the author applicable to the generality of cases, whether they concerned wounds of Stenson's duct or the masseteric lobes of the parotid gland; the author employed this method four times, always with success), the transplantation of Stenson's duct (this procedure is contra-indicated where the tissues are cicatricial, but Dieulafé advocates it for all cases where there can be found an appreciable segment of the posterior, *i.e.* proximal, end of the duct, and where this can be fixed to a healthy mucosa, the author has had one failure, a civilian case, and two successes, military cases, by this method), the creation of an artificial duct at the expense of the mucosa, and finally, the suppression of the parotid secretion. The last method is not recommended personally by Dieulafé. However, to accomplish this the duct may be ligated.

Remarks on Dichloramine-T. BY EDWARD
K. DUNHAM.

Dichloramine-T is an aromatic chloramine containing a little over 29 per cent. of chlorin. Its systematic name is toluene para-sulfon-dichloramine. It is only slightly soluble in water, but freely soluble in certain oils. This property is of essential importance in its use as an antiseptic.

Dunham prefaces his discussion of this representative of the newer antiseptics with a brief survey of the whole subject of the antiseptic treatment of wounds from the laboratory viewpoint. For successful disinfection, three conditions must be met: (1) Contact of antiseptic with infecting organisms; (2) time during which this contact is maintained, and (3) adequate mass, or concentration of the antiseptic at the points of contact. But little dependence can be placed upon the power of penetration of any known antiseptic, least of all when these are chemically unstable in the presence of substances occurring in wounds.

There are three things of prime importance that should be known about an antiseptic before it is chosen as appropriate for a given purpose, because the way in which it should be used to obtain the best results depends on such knowledge as—(1) The speed or rate of disinfection. (2) the stability of the substance under the conditions of its use, since this affects the duration of disinfection, and (3) the permissible concentration, for this determines the mass of antiseptic that can advantageously be employed.

The speed of disinfection is enormously influenced by the medium in which the antiseptic acts. In a medium of equal parts of blood serum and muscle extract, the disinfectant action of the members of the chlorin group were extremely rapid.

All the members of this group have a direct chlorinating and an indirect oxidizing power. The germicidal action of chlorin antiseptics is not specific, but is incidental to the high reactivity of this group of compounds. In other words, the efficiency of this group is a function of their chemical instability and high affinity for many other substances, and consequently to secure the best results pro-

vision must be made for an adequately frequent renewal of the antiseptic. The chlorin antiseptics have a very striking detoxicating effect upon wounds, in addition to germicidal and deodorant action.

The third factor, the permissible concentration in which these antiseptics can be applied, and therefore the mass entering into the above reactions, can only be determined by clinical experience. Solutions of dichloramine-T in oil can be used in concentration up to 20 per cent. if need be, thus introducing an extraordinary mass of antiseptic at a single application. This abundant and apparently excessive mass can become effective without undue irritation. When proteins are present—and they invariably are in the secretions of wounds—the amount of active chlorin transferred from the oil solution is amply sufficient for rapid action. This action is continuous, not intermittent, and the renewal of the antiseptic coming into play in the secretions is automatic, and persists until the store in the oil has been exhausted.

The Incidence of Chronic Focal Infection in Chronic Diseases. BY LOVELL LANGSTROTH.

This report is a brief summary of the data, pertinent to the doctrine of focal infection, afforded by the medical clinic of the University of California Hospital. The subject was of interest not only because it explained the cause of diseases whose etiology was hitherto unexplained, but also because it opened up a hopeful field in respect to therapeutics.

Langstroth summarizes his observations as follows: 84 per cent. of ulcer (gastric and duodenal) patients, 66 per cent. of acute or subacute cases of arthritis, 73 per cent. of the chronic cases of arthritis, and 100 per cent. of the gall-bladder cases, have been associated with chronic focal infections.

These figures are imposing until we realize that they are percentages based upon a total of thirty cases of gastric and duodenal ulcer, of twelve cases of acute or subacute arthritis, of forty cases of chronic arthritis, and of four cases of chronic gall-bladder disease.

In the face of this it must be granted

that—"The figures do not, of course, prove any causal relation between chronic focal infection and the various chronic diseases mentioned." It is just this proof which is the crux of the whole question.

What is of special interest to the dentist in this paper follows: "In a number of cases the therapeutic results have been good; in a few cases they have been brilliant. The foci which lend themselves most readily to our work are the teeth and the prostate. On two occasions we have insisted on the removal of teeth because the [roentgen] plate showed a distinct area of rarefaction at the root-apex, and pus has not been found. *Even with a positive report from the roentgen-ray department, one should rely on the judgment of a competent dental surgeon when he declares the tooth to be, nevertheless, sound.*"

The following is probably one of the brilliant results referred to above: One of the patients was a girl of seventeen years, with a subacute arthritis of the right foot of several months' duration. The joint improved the day after drainage of an alveolar abscess by extraction, and in ten days the patient wore a shoe for the first time in three months. An intensive and complete study of a concrete case such as this would be far more opportune and welcome than the elaborate compilation of statistics.

[*Science*, November 9, 1917.]

Anesthesia and Respiration. By A. R. C. HAAS.

It seems necessary to establish with certainty the effect of anesthetics upon respiration before a satisfactory theory of anesthesia can be formulated. Haas has measured the change in the hydrogen-ion concentration of sea-water produced by the respiration of the marine alga, *Laminaria*.

Experiments were carried on with sea-water containing the following substances: Chloral hydrate, novocain, ether, caffein, ethyl bromid, formaldehyd, chloroform, acetone, and ethyl alcohol.

"It was found that whenever the concentration of anesthetic is sufficiently strong to produce any measurable result, the initial effect is always an increase of respiration, which may either remain approximately constant over a large number of periods and then gradually decline, or the increased rate of respiration may fall very rapidly below the normal when the concentrations of anesthetic are too great. No decrease is observed with low concentrations which are not toxic. These facts contradict the theory of Verworn that anesthesia is a kind of asphyxia, for his view is based on the assumption that anesthetics decrease respiration."

PERISCOPE

Vincent's Angina.—Dr. Thomas Hubbard of Toledo states that reports of fatalities, in a disease that was usually transient and curable, indicate that a large number of cases are not diagnosed. Laboratory study of all ulcers and false membranes is necessary to positive, timely diagnosis. Perborate of sodium is an efficacious local medicament. The nascent hydrogen dioxid penetrates and disintegrates necrotic tissue, and is, theoretically, an ideal inhibitor of anaerobic bacterial growth. The local treatment resolves itself into careful applications limited to the diseased tissue. The glycerol of iodine—iodid of zinc 2, iodine 3, aqua destillata 5, glycerin 10—applied to the tonsil crypts was probably

the most efficacious antiseptic. Theoretically the arsenical group is specific in action, and the writer believes that experience is proving favorable. He reports a case which presented a hopeless condition prior to the administration of neosalvarsan, and the improvement following was comparable only to that in diphtheria cases following a proper dose of antitoxin. In cases that did not yield promptly to this treatment cacodylate of sodium should be given, 2.5 to 5 grains, repeated in twenty-four or forty-eight hours, if the kidneys are not affected. In the malignant type, not improving under the above treatments, neosalvarsan 0.6 gram is given intravenously.—*N. Y. Med. Journal*.

A Hint on Mixing Cement.—For the proper mixing of cement a strong, pliable, rather long-bladed spatula gives the best results. It should be used rapidly with long, strong strokes, exerting considerable downward pressure, thus compelling a thorough mechanical mixing, which is the only way to create the opportunity for an accurate chemical union, which is very necessary if the maximum density and adhesiveness is to be attained.—*Oral Health*.

Removing Blood Stains.—To remove blood stains use a concentrated solution of chloral hydrate, from 70 to 80 per cent. Not only recent blood stains on linen, but stains existing for from ten to twenty years, first moistened with a drop of acetic acid and then soaked for some hours in a chloral solution are said to be perfectly removed. Blood stains on white materials may also be removed by treatment with hydrogen dioxide solution. It may take some hours to act if the stain is old.—*Druggists' Journal*.

Annealing Lingual Bars.—In the construction of lingual bar cases for partial lower dentures where the bar is to be soldered to gold saddles, the bar should be thoroughly annealed after bending and final adjustment has been completed, otherwise the heating in soldering will cause the bar to spring, and the case will not go back to place properly on the cast, and failure will result in the mouth. This result will also obtain in vulcanite cases unless the bar is annealed before final adjustment.—VICTOR H. FUQUA, *Dental Review*.

Local Anesthesia for Painless Operating.—Because of the initial pain accompanying the insertion of the needle, because of toxic symptoms observed, because of after-pain and soreness, and because of occasional sloughing of tissue and even abscess formation occurring at the site of injection, many otherwise conscientious operators have shunned the hypodermic syringe and the local anesthetic solution, thereby inflicting untold agonies that might have been avoided had they mastered the technique of our modern methods of induction. Every dentist can do better and more thorough work if he can operate painlessly, and incidentally, patients may use up their nervous energy in much more useful pursuits than that of enduring unnecessary pain incident to the excavation of sensitive cavities, the extirpation of vital pulps, or the extraction of teeth.—P. G. PUTERBAUGH, *Dental Review*.

Iodin as an Antiseptic.—Iodin is one of the most widely used and most useful of antiseptics. It was introduced as a skin disinfectant by Stretton in 1909, and for this purpose is undoubtedly of great value. It has been found much too irritating for repeated application to open wounds, and it is said that severe neuritis has been observed as a result of its use. Its strong coagulating action upon protein is also an objectionable feature. "In general, it may be said that iodine will be found most useful when the conditions are such that rapid and complete sterilization may be effected by a single application, as in skin disinfection or small surface wounds."—*Amer. Journ. of Clin. Medicine*.

Bleaching Teeth.—One of the very best bleaching agents for discolored teeth is 25 per cent. pyrozone. The root should be filled, and a pellet of cotton saturated with the pyrozone should be placed in the cavity and sealed with cement. It may be left two or three days, and if a tooth can be bleached at all, it will be bleached by this method. The pyrozone comes in sealed glass tubes. Care must be exercised in opening the tube. It should be chilled on ice and wrapped with a towel, letting the narrow end of the tube extend from the towel. This can then be snipped off with pliers, and the contents of the tube poured into a clean glass-stoppered bottle. A second application of the pyrozone may be necessary in deeply discolored teeth.—EDITORIAL, *Dental Review*.

An Interesting Case of Hypertrophied Tissue.—Miss X., about forty years of age, came to my office with the roof of her mouth covered with hypertrophied tissue in the form of soft teats as big as the end of the little finger. My diagnosis was that the plate was ill-fitting and did not go up into the arch in front, but did in the back, thus forming a vacuum. As "Nature abhors a vacuum," the tissues had grown down trying to fill it up. I cocaineized and removed all the large teats possible, cauterized the remaining tissue with 4 per cent. AgNO₃, and applied glycerite of tannin. I then built up the plate with modeling compound until it caused an even pressure on the affected area, thus causing absorption. I saw the patient every few days, and cauterized and built on to the plate until I got her mouth into absolutely normal condition. Then I made a well-fitting plate without a vacuum chamber, and she has had no further trouble.—R. B. ENSON, *Proc. Harriet Newell Lowell Society for Dental Research*.

Atmospheric Pressure in the Retention of Dentures.—Atmospheric pressure, contrary to the opinion of many, is only a negligible factor in the retention of dentures, it being dependent upon a vacuum, or near-vacuum, under the plate. So long as this space remains under the plate atmospheric pressure has some bearing on the retention, depending upon the degree of vacuity obtained, fifteen pounds of pressure to the square inch being the weight of a column of air on a surface from under which all air has been excluded. But the vacuum space cannot be permanent unless it is placed over a hard, unyielding area, in which case it acts as a relief; otherwise the space is soon filled in with the yielding tissue, and the influence of atmospheric pressure is lost, leaving the denture to be retained by the true principle, adhesion by contact.—E. B. OWEN, *Dental Summary*.

Making a Workable Cast.—After employing the time, skill, and care necessary to produce a good impression, don't spoil it by using plaster of Paris for the cast. I am not condemning plaster too severely, for many good dentures have been made over it, but knowing its properties of expansion and compressibility as we do, why take chances with it when such materials as Spence's plaster and Weinstein's artificial stone are to be had?

The technique of manipulating these materials is too well known for discussion here. The writer personally prefers Spence's plaster, which must be manipulated and jolted into the impression for two or three minutes in order to give a smooth cast. This jolting requires that some sort of a matrix be built around the impression to confine the cast material. This matrix serves also to preserve the contour of the impression in the cast, which is necessary if we are going to extend the denture accordingly.—E. B. OWEN, *Dental Summary*.

Teeth Do Not Control Mandibular Movement.—When building up cusps and carving fissures it will be well to remember that the teeth do not control the mandibular movements. If a cusp or part of a crown is not in harmony with the arcs through which the mandible sweeps in its movements it will wear off, or act as a lever to loosen the tooth upon which it is found. When several teeth are malposed they will to some extent limit the movements of the mandible, but never control it. The mandible will move as freely and as far as the muscles will pull, or the patient chooses to move it, but in all these movements it sweeps through certain

arcs of circles that are in harmony with the peculiarity of the anatomic of the case, without any regard to the occlusion or the occlusal surfaces of the units that make up the two arches. If any cusp or series of cusps are so placed that they interfere with these movements, they will be reduced to a point where they are in harmony, or the tooth of which they are a part will be exfoliated, while the mandible swings merrily on in its accustomed arcs.—F. W. FRAHM, *Pacific Dental Gazette*.

Ionization in the Treatment of Neuralgia.—Ionization has been successfully used for the treatment of trigeminal neuralgia. The technique consists in covering the whole affected area of the face with a folded cloth pad saturated with warmed solution of two per cent. sodium salicylate. On this is fitted a metal electrode covered with felt, which is securely bandaged in position throughout the application. The indifferent electrode, which is also well covered with lint and moistened with sodium chlorid solution, is placed on the chest, or under the shoulders. The salicylic ions are anions, they are therefore repelled from the negative pole, which is attached to the electrode on the face. The current is turned on gradually and the patient can usually bear 20 to 30 m.a.; the application should last for thirty minutes, and may be repeated three times a week.

Great care must be taken to secure the terminals, so that there is no possibility of sudden break of current.

Quinin ions have also been used successfully for trigeminal neuralgia with the same technique, but the positive pole is here necessary to introduce these cations.—E. STURRIDGE, *Dental Items of Interest*.

Use of the Toothbrush.—The chief benefits derived from the use of a toothbrush are that it acts as a series of fine toothpicks, thereby removing a part of the loose debris, and that the massaging produces a more healthy condition of the gums. Massaging of the gums, however, can be carried to excess. I do not like to see the gums present a hard, leathery, mottled, pink surface, for this caloused appearance is the result of severe rubbing. There is not good circulation, and infection followed by serumal deposits usually occurs sooner or later, and works rootwise under this kind of tissue. Gum tissue should lie over well-formed bony structure, and should have a good, bright, healthy color, and a network of fine capillaries showing plainly just under the surface. I do not mean hyperemia, but just a good healthy

circulation. As far as I have been able to observe, daily massaging with cotton rolls or cheesecloth napkins increases circulation, but does not cause the gums to become calloused. It is better to take toothbrushes away from patients, if they cannot learn to handle them properly, and have them depend upon the polisher, dental floss, and cotton rolls, for with these they will not injure their teeth or gums.—FRANK H. SKINNER, *Dental Summary*.

Leucoplakia Oris.—Sometimes the mucous membrane of the cheeks, lips, and tongue develops a tendency to take on a grayish-white coating, which is at times irregularly diffused, or decidedly patchy or flaky in appearance. This condition is called leucoplakia oris. It bears a close resemblance to the so-called leucoplakia of syphilis, except that the mucous membrane is quite smooth, and is devoid of the scarlike irregularities of the latter process. A serological examination will establish readily the identity in doubtful cases. The cause of this simple form of leucoplakia is very obscure. Syphilis and immoderate use of tobacco are regarded as predisposing influences by many. On the other hand, leucoplakia is often observed in women who have never incurred an infection of syphilis, and who likewise are not addicted to the use of tobacco. Some of the cases probably are predisposed by chronic gastric hyperacidity, and to the local irritation incident to overindulgence in pungent, acrid, highly spiced foods and condiments. This condition may become exceedingly pronounced in extreme cases, and not infrequently becomes transformed into well-defined malignancy. Its recognition and significance is within the pale of dentistry, with an incurred obligation of proper care and safe conduct.—M. L. HEIDINGSFELD, *Dental Summary*.

Reinforced Silicate Cement Filling.—The future favorite filling for certain selected anterior cavities will be the filling made by grinding a piece of porcelain of proper shade to match the tooth to be filled, and then setting the porcelain with silicate cement.

The piece of porcelain need not be ground so accurately as to fit the cavity perfectly, as the silicate will fill the inequalities and give a harmonious appearance. The porcelain, however, should be large enough to give the tooth its general contour, make a perfect contact point with the approximal tooth, and should form an occlusion with the opposing teeth when the jaw is closed. The porcelain should be of sufficient size to reproduce the general contour of the tooth, so that it will not be necessary for the silicate

cement to run over the edges of the porcelain, for the reason that the thin edges will break off later.

This kind of filling has many advantages, and overcomes nearly all the weak points of the silicate filling, such as lack of strength to retain the contact point and insufficient strength to hold on incisal angles or occlusal surfaces.

The inlays are cut from the part of a porcelain tooth which corresponds to the part to be replaced. A broken tooth or a diastoric tooth, or any pieces of a tooth, may be used, just so a piece is obtained that approximately corresponds to the cavity you wish to fill.—E. E. HAVERSTICK, *Dental Summary*.

Indications and Contra-indications for Local Anesthesia.—Almost everyone who has seriously entered the practice of conductive anesthesia has found that with increasing experience in its use he employs it more and more, to the exclusion of the commonly practiced infiltrative type. This is accounted for by the comparative painlessness of the needle insertion and the injection, the small amount of solution required, the absence of after-pain and soreness, and the absolute anesthesia obtained. Patients upon whom it has been used for cavity preparation or surgical procedures are pleased with the results, and request its use on subsequent occasions, and that encourages one to use it with increasing frequency as time goes on. It is not recommended over nor will it ever supplant nitrous oxid for the highly nervous, uncontrollable neurasthenic who dreads operations; for the physically exhausted individual who has been in pain for a number of days; for the child with whom it is difficult to reason, nor for extractions in acute abscess conditions. But for the preparation of the sensitive cavity that does not respond to the ordinary methods of desensitization, for the removal of vital pulps, for root amputations, for extractions, for prolonged and complicated operations such as the removal of unerupted and impacted teeth, for maxillary sinus operations, for the reduction of fractures of the mandible, and for the removal of tumors and cysts about the jaws, it gives complete anesthesia. The patient can be placed in any position in the dental chair that is most convenient to the operator; there is no aspiration or swallowing of blood or mucus, and no nausea, vomiting, or prostration after the operation is over. In fact, the anesthesia will usually last until the patient reaches home, which in itself is highly desirable.—P. G. PUTERBAUGH, *Dental Review*.

Three Bronchoscopic Cases the Result of Dental Procedure.—Dr. Burt R. Shurly of Detroit states that statistics show that possibly 600 cases of the sudden inhalation of foreign bodies during dental procedure have occurred in the United States and Canada. It was therefore important to devise a special protective device.

In the first case the patient stated that her cough dated immediately after extraction of a tooth under nitrous oxid anesthesia. A radiogram showed the tooth. The trachea was not cocaineized, and bronchoscopy failed. Tracheotomy and subsequent bronchoscopy resulted in removal and cure.

In the second case the cough followed tooth extraction under nitrous oxid. There was a marked odor of rubber. The air supply of the lower part of the lung was cut off, and a piece of hard rubber, which had been part of a dental mouth-gag, was brought up to the trachea, slipped from the forceps, but fortunately was coughed up soon after by the patient.

In the third case the patient was receiving treatment from a dentist preparatory to filling the root-canal of a tooth. The canal was treated with a dental broach, which was held between the thumb and forefinger during the process of application. This tiny instrument suddenly slipped and was inspired into a lower division of the left bronchus. After this remained in the bronchus for ten days, the X-ray examination with antero-posterior and lateral plates showed a shadow in the lower left thoracic region, which it was believed was a metallic foreign body in the lower left bronchus. After a thorough application of novocain to the respiratory passage, with cocaineization advanced as the tube was introduced, and followed to within the lowest terminations possible, this foreign body was extracted, which was pointing with the needle part upward. The patient recovered completely without symptoms.

Interesting cases of the swallowing or inhaling of various articles of dental equipment were reported by Dr. Thomas Hubbard of Toledo, Dr. Harmon Smith of New York, Dr. Carl E. Munger of Waterbury, Conn., Dr. Albert C. Getchell of Worcester, Dr. Bryson

Delavan of New York, Dr. Emil Mayer of New York, Dr. Robert C. Lynch of New Orleans, and Dr. Stanton Friedberg of Chicago.—*N. Y. Med. Journal.*

Technique for Packing Amalgam.—Contrary to the usual method of removing the excess mercury before packing into the cavity, this semi-plastic mass is used for producing the filling, as it is practically impossible to pack amalgam into the cavity and adapt the margins when the excess mercury has been removed before the packing begins. The mixed amalgam should never be cut into squares and placed on the operating table, but an assistant should keep the mass moving between the fingers all the time. Portions of this plastic mass are carried to the cavity and patted down by numerous taps with the condensing instrument, thus causing the amalgam to flow into the cavity. Large instruments are used for this purpose, but the finer adaptation is done with a much smaller instrument. The excess mercury is removed from the filling during the packing process. It is readily seen that it is much easier to adapt a plastic mass to the margins than one which is so stiff that it is impossible to make it flow. It is just as difficult to adapt amalgam to the margins of a cavity as it is gold, and no amount of burnishing will make a margin tight unless the material has been adapted during the process of packing.

When the amalgam has been carried to the bottom of the cavity by the larger instrument, a smaller one, having a tread of about two millimeters, is used for adapting the material to the margins. I prefer the square-end serrated instruments. The margins are carefully gone over, stepping one-half the width of the instrument from the center toward the buccal and lingual margins. This stepping brings the excess mercury to the surface, where it is easily removed with the packing instrument. Another layer is carried down in the same manner in fairly large quantities, tapping it down with light blows with a four-millimeter plugger, and packing down each layer with a smaller instrument. Remove the excess mercury when the margins are all covered.—THOS. P. HINMAN, *Dental Items of Interest.*

HINTS, QUERIES, AND COMMENTS

Casting Zinc Electrode Points for Ionization.

TO THE EDITOR OF THE DENTAL COSMOS:

IN the ionization of root-canals the zinc electrode points are easily made by casting with any centrifugal casting apparatus as follows:

Fill an investment ring with a fine investment, and insert from ten to fifteen ordinary needles the size you wish the points to be. Allow the investment to harden, remove the needles, dry out, and cast.

FRED. A. KOTTS.

Toledo, Ohio.

OBITUARY

Dr. John R. Callahan.

[SEE FRONTISPICE.]

DIED, Tuesday, February 12, 1918. at Cincinnati, Ohio, of apoplexy, in his sixty-fifth year. JOHN ROSS CALLAHAN, D.D.S.

Dr. Callahan was born June 28, 1853, at Higginsport, Ross county, Ohio, the son of Dr. Dennis Callahan and Sarah Ross Callahan. Dr. Callahan's father was a minister in his early years, and later became a physician and dentist, which professions he practiced until the time of his death.

Dr. Callahan's early education was obtained in the Hillsboro, Ohio, schools. He began the study of dentistry under Dr. John Ellis, who was associated with his father in Hillsboro in the early '70's. He later entered the Philadelphia Dental College, and was graduated from that institution in 1877. After his graduation he began the practice of his profession in San Francisco, Cal. Two years later he returned to Hillsboro, Ohio, and continued the practice of dentistry at that place until 1890, when he removed to Cincinnati, Ohio, where he succeeded to the practice of Dr. C. R. Taft, brother of the late Jonathan Taft, and practiced until the time of his death.

Dr. Callahan was active in national and

local dental affairs, being a member of the National Dental Association, and of the Ohio Dental Society, which latter he served for several years in the capacity of secretary, and in 1891 as president. He was a member of the Cincinnati Dental Society, and president in 1906-07.

Dr. Callahan was for many years head of the dental department of the Cincinnati General Hospital, at which institution he did very valuable work, and was largely instrumental in bringing about a closer co-operation between the dental and medical professions in Cincinnati and vicinity. He was director of the Research Club of Cincinnati, a member of the Cincinnati Research Society, and honorary member of numerous state and local societies.

Dr. Callahan possessed naturally a scientific turn of mind, and from the beginning of his career as a dentist was deeply interested in research work. As a result of his studies and investigation in the treatment of root-canals he gave to the profession a method, now known by his name, for the treatment of putrescent root-canals by means of sulfuric acid,* which is today one of the most

* "Sulfuric Acid for Opening Root-canals," DENTAL COSMOS, 1894, pp. 329 and 957.

successful and generally used methods for the purpose of opening and cleaning root-canals. He later gave to the profession a method of filling root-canals with rosin,* which is in general use at the present time.

In recognition of the valuable scientific research work which Dr. Callahan did, the results of which he so freely gave to the profession, the New York State Dental Society in 1917 presented to him the Jarvie Fellowship Medal, one of the highest honors that can come to a member of the dental profession in America. At this same meeting of the New York Dental Society at which he received the Jarvie Fellowship Medal, he presented a paper on "Logical Asepsis in Dental Practice,"† in which he gave the results of extensive experimental research work in an effort to impress upon the profession the importance of asepsis in dental practice.

Dr. Callahan was married to Miss Sarah Ann Stephenson, Hillsboro, Ohio, in 1891. He is survived by a widow and three children. The funeral services were held in the Cincinnati Crematory, Friday, February 15, 1918, after which his body was cremated.

The following editorial tribute to Dr. Callahan, in the Cincinnati *Times-Star* for February 15th, is a just appreciation by one who knew Dr. Callahan both professionally and as a friend during many years:

"The death of Dr. John R. Callahan is a great loss to dental science. Dr. Callahan's professional activities took him far beyond the routine of his practice. He labored for the general advancement of his profession, and had no small share in widening the scope of dentistry until it became one of the important factors in general diagnostics. From his laboratory came many contributions to dental science, the harvest of experimentation as unselfish as valuable. The scientific imagination was one of Dr. Callahan's attributes, the ability to see beyond the immediate causes into the causes of causes, to trace symptoms to their source instead of being satisfied with superficial manifestations.

"There is something heroic about a pro-

† "Logical Asepsis in Dental Practice." *DENTAL COSMOS*, 1918, p. 31.

fessional career that so quietly contributes to the general good of humanity. There is no perfervid appeal to 'the peepul' to recognize service in their behalf. The emoluments are in no sense commensurate with the achievements. The effort finds its reward largely in the effort itself, and in its scientific fruition. Any praise from the outside world comes largely from the few possessed of the special knowledge that equips them for appreciation.

"Such was Dr. Callahan's career—the unselfish labor of a scientist in humanity's behalf. He worked hard, accomplished much, and received his meed of praise from those familiar with his achievements. The greatest tragedy of his death lies in the things that he would still have accomplished, and which he was forced to relinquish to other heads and hands."

The following resolution was passed by the Chicago Dental Society on the death of Dr. Callahan:

Whereas, the Chicago Dental Society have learned of the sudden death of Dr. John R. Callahan; and

Whereas, Dr. Callahan always stood for the highest and best in the dental profession; and

Whereas, he was conspicuously known for his ability, integrity, and scientific attainment; therefore be it

RESOLVED, That we, the members of the Chicago Dental Society, wish to go on record as expressing our loving memory of his faithful and fruitful life and our sincerest sorrow at his death.

W. H. TAGGART, *Chairman*,
C. N. JOHNSON,
T. L. GILMER,
Committee.

Dr. Joseph Lemuel Mewborn.

DIED, Saturday, December 15, 1917, at his home in Memphis, Tenn., from acute indigestion, after an illness of only three days, in his eightieth year, JOSEPH LEMUEL MEWBORN, D.D.S.

Dr. Mewborn was born in Madison county, Ala., near Huntsville, on March 3, 1838, the son of Charlton Augustus and Mary Jane (Long) Mewborn. His early education was procured in the schools of his vicinity, and later in the Macon Masonic College and the LaGrange Synodical College of Tennessee.

When the civil war broke out, Dr. Mewborn enlisted in the Confederate army, and was soon made a second lieutenant in the 13th Tennessee Infantry. He was present at the first battle of Manassas. In the last year of the war he was captured, and it was while

former preceptor, Dr. Johns, at Somerville. A few years later he removed to Memphis, Tenn., where he continued to practice until the time of his death. He was in continuous practice for fifty-two years.

Dr. Mewborn was a member of the Tennes-

DR. JOSEPH LEMUEL MEWBORN.

a prisoner at Johnson's Island on Lake Erie that he began the study of dentistry.

At the close of the war he continued the study of dentistry under Dr. W. R. Johns of Somerville, Tenn. He later entered the New York College of Dentistry, and was graduated from that institution with high honors in 1871. Immediately after his graduation he entered the practice of dentistry with his

see State Dental Association, serving it in the capacity of vice-president and president; a member of the American Dental Association, the Southern Dental Association, and the Southern Branch of the National Dental Association. He was one of the organizers of the Memphis Dental Society, and served on the Tennessee State Board of Dental Examiners for twelve years.

Dr. Mewborn was always eager and willing to serve in any capacity for the upbuilding of his profession. He was a close student of dentistry, and next to his family and home he loved his colleagues and the dental profession. He played an important part in securing legislation in Tennessee, governing the practice of dentistry, which has placed the state second to no other commonwealth regarding the high standards which must be attained by all members of the profession.

One of the most impressive expressions of the high regard in which Dr. Mewborn was held by his associates was shown him by the dentists of Memphis upon the occasion of a banquet given by the Memphis Dental Society on May 12th in his honor. After many beautiful expressions of love and esteem from those present, he was presented with a handsome gold-headed cane bearing the following inscription: "Presented to Dr. J. L. Mewborn by the members of the Memphis Dental Society in token of their high esteem for his long years of loyalty and unparalleled usefulness to the profession, 1912." This occasion always remained in Dr. Mewborn's memory as one of the happiest events of his life, and one to which he often referred with pride.

Dr. Mewborn was married to Miss Mary Anne Mathews November 20, 1866, in Macon, Tenn. He is survived by his wife and eight children. The funeral services were held at his home December 17, 1917, and interment took place in the mausoleum at Forest Hill Cemetery, Memphis.

The Memphis Dental Society passed the following memorial resolutions on the death of Dr. Mewborn:

In Memoriam

DR. JOSEPH LEMUEL MEWBORN.

"Let me not follow the glamor of the world,
But walk calmly in my path.

Give me a few friends who will love me
For what I am; and keep ever burning
before

My vagrant steps the kindly light of hope;
And though age and infirmity overtake me
And I come not in sight of the castles of my
dreams,

Teach me still to be thankful
For life, and for time's golden moments
That are fond and sweet; and may the
evening

Twilight find me gentle still."

Whereas, by the death of our honored and esteemed colleague, leader, and friend, Dr. Joseph Lemuel Mewborn, the Memphis Dental Society feels that it has been sorely bereaved in a personal manner as well as professionally: Personally, because of his courteous and cheerful conduct in our everyday social relations. His attitude toward us has ever been of the most kind and considerate nature, and will remain with us as a precious memory. Professionally, we shall miss his wise and experienced counsel and his deep interest in and devotion to our work. He was ever ready to make needed sacrifice of time and talent for his beloved profession, to which he gave so many years of valuable service.

Perhaps the feature of his character which was most admirable was the impeccable soundness of his moral fiber. Indecision and indirection were foreign to his nature, and to all the activities of his long, honorable, and useful career he brought sterling integrity and absolute loyalty to truth.

Uniformly urbane and courteous in social intercourse, he was in the highest sense a gentleman. When aroused, he had at command large potencies of incisive speech with which to enforce a lesson, expose a fallacy, or condemn a wrong. A veteran in dentistry, he was a pioneer in all those progressive advances which finally culminated in its organization and recognition as a distinct professional body. And

Whereas, in the passing away of our beloved friend we have the assurance that God our all-wise Heavenly Father has taken him unto His bosom; therefore be it

RESOLVED, That the Memphis Dental Society extends its sincere sympathy to Mrs. Mewborn and to the sons and daughters in their bereavement, which is the sorrow of each and every member of the society and the profession at large. We wish to express our high regard for the worth and character of this loving and lovable man.

At the banquet of the Golden Jubilee of the Tennessee State Association, 1917, Dr. Mewborn closed his memorable and beautiful response to the toast "Reminiscences of Long Ago," with the following lines, which seem to have been anticipatory and prophetic:

Here is a toast I want to drink
To the fellow I'll never know—
To the fellow who'll take my place
When it's time for me to go.

I've wondered what kind of a chap he'll be,
 I've wished I could take his hand,
 Just to whisper, "Wish you well, old man!"
 In a way that he'd understand.

I'd like to give him the cheering word
 The word I've longed to hear;
 I'd like to give him the warm handclasp
 When never a friend seems near.

I've learned my knowledge by sheer hard
 work,
 And I wish I could pass it on
 To the fellow who'll take my place
 Some day, when I am gone.

Then here's to your health, old chap!
 I drink as a bridegroom to his bride:
 I leave an unfinished task for you,
 But God knows that I have tried.

I've dreamed my dreams, as all men do,
 But never a word came true;
 My prayer today is that all my dreams
 May be realized by you.

And we'll meet some day in the Great
 Unknown,
 Out in the realms of space:
 You'll know my clasp as I take your hand
 And gaze in your tired face.

Then all your failures will be success
 In the light of the new-found dawn!
 So I'm drinking your health, old chap,
 Who'll take my place when I'm gone.

Dr. Robert Hopkins Moffitt.

DIED, Wednesday, January 16, 1918, at his home in Harrisburg, Pa., of pneumonia, in his seventy-fifth year, ROBERT HOPKINS MOFFITT, D.D.S.

Dr. Moffitt was born in Springfield, Ohio, May 3, 1843, the son of John J. and Charlotte Epley Moffitt. His parents, while he was still a boy, moved to Cadiz, Ohio, where he obtained his early education.

Dr. Moffitt began the study of dentistry when a young man under the tutelage of his father. He established himself in practice in York, Pa., shortly before the civil war, and remained there until 1862, when he enlisted in the Ninth Ohio Cavalry and served in the medical corps of the Federal army during three years of the war.

After the civil war closed he went to Harrisburg, Pa., where he again took up the

practice of dentistry, attending the Philadelphia Dental College later and being graduated from that institution in 1874. Dr. Moffitt gave up the practice of dentistry some twenty years ago, and devoted his time to business, banking, real estate, etc.

Dr. Moffitt was a pioneer in porcelain and continuous gum-work, with his brother, Dr. J. W. Moffitt, the two sons having obtained their early training in this work in West Virginia, from their father, who was a dentist and Methodist minister.

Dr. Moffitt was one of the founders of the Harris Dental Society, a member of the Lebanon Valley Dental Society, and a member of the Pennsylvania State Dental Society, serving the latter in the capacity of secretary in its early days, and aided materially in procuring the legislation which resulted in the establishment of the state society.

Dr. Moffitt was active in church work as well as in business, in the later years of his life. He helped to found the West Market Mission, which afterward became the Westminster Presbyterian Church at Harrisburg. He was a director in the Commonwealth Trust Co. and president of the board of trustees of the Market Square Presbyterian Church. He was largely interested in civic affairs, and took an active part in real estate developments in various sections of the city.

He was married April 26, 1870, to Miss Rebecca Whitman in Harrisburg, Pa. He is survived by seven children, one of whom, Dr. G. R. Moffitt, is a practitioner of medicine in Harrisburg, and another, Dr. J. J. Moffitt, a practitioner of dentistry in Harrisburg.

The funeral services were held January 19, 1918, and interment took place in the Harrisburg Cemetery.

"In Memoriam" Resolutions.

Dr. Fred M. Smith.

THE following "in memoriam" resolutions were adopted by the Academy of Stomatology of Philadelphia, March 6, 1918:

Whereas, death has removed from us our friend and fellow-member, Dr. Fred Maurice Smith; and

Whereas, the dental profession by his death has lost one who was conscientious and up-

right in all that pertained to its usefulness and influence, and society, through his clear judgment and unselfish interest, a useful member; therefore be it

RESOLVED, That the Academy of Stomatology, deploring his death, extends its sympathies to his bereaved wife and mother. It will ever bear in memory its association with him. And be it

RESOLVED, That a copy of these resolutions be sent to the bereaved ones, that a record of them be made in the minutes of the Academy, and a copy sent to the DENTAL COSMOS for publication.

J. V. MERSHON,
R. G. BEALE.
S. B. LUCKIE.
Committee.

At the annual meeting of the Dental Society of Chester and Delaware Counties, held January 23, 1918, the society adopted the following resolutions:

Whereas, the Supreme Ruler of the universe has, in His infinite wisdom, removed from the scene of his earthly labors our esteemed friend and colleague Fred Maurice Smith; and

Whereas, The Dental Society of Chester and Delaware Counties, of which he was a useful and honored member, recognizing his faithfulness as a member, desires to record its appreciation of him as a man, and its sense of sorrow and loss at his death; therefore be it

RESOLVED, That this society extends to the widow and mother of our deceased member its sincere sympathy in their bereavement; that this resolution be spread upon the minutes of the Dental Society of Chester and Delaware Counties, and that a copy be forwarded to the DENTAL COSMOS for publication.

G. B. LUCKIE.
ROBERT M. SCOTT,
D. W. GODON,
Committee.

DENTAL LEGISLATION

Proposed Legislation for the Navy Dental Corps.

BILL INTRODUCED IN THE SENATE [S. 3749] BY SENATOR TILLMAN, AND IN THE HOUSE OF REPRESENTATIVES [H. R. 10724] BY MR. DYER.

A BILL

TO REORGANIZE THE DENTAL CORPS OF THE NAVY, AND FOR OTHER PURPOSES.

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled,

That the Act approved August twenty-ninth, nineteen hundred and sixteen, entitled "An Act making appropriations for the Naval Service for the fiscal year ending June thirtieth, nineteen hundred and seventeen, and for other purposes" (Statutes at Large, volume 39, chapter 417, pages 573 and 574) be, and the same is hereby, amended by striking out all of said Act following the caption "Naval Dental Corps." on page 573. but preceding

the caption "Dental Reserve Corps." on page 574, and by substituting therefor the following:

That the President of the United States is hereby authorized to appoint and commission, by and with the advice and consent of the Senate, dental officers in the Navy at the rate of one for each thousand of the total authorized number of officers and enlisted men of the Navy and Marine Corps, in the grades of assistant dental surgeon, passed assistant dental surgeon, and dental surgeon, who shall constitute the Naval Dental Corps, and shall be a part of the Medical Department of the Navy. Original appointments to the Naval Dental Corps shall be made in the grade of assistant dental surgeon with the rank of lieutenant (junior grade), and all dental officers now in the Dental Corps, ap-

pointed under the provisions of the Act of Congress approved August twenty-ninth, nineteen hundred and sixteen (Statutes at Large, volume 39, page 573), or who may hereafter be appointed, shall take rank and precedence with officers of the Naval Medical Corps of the same rank according to the dates of their respective commissions, and dental officers shall be eligible for advancement in grade and rank in the same manner and under the same conditions as officers of the Naval Medical Corps with or next after whom they take precedence, and shall receive the same pay and allowances as officers of corresponding rank and length of service in the Naval Medical Corps up to and including the rank of lieutenant commander: *Provided*, That dental surgeons shall be eligible for advancement in pay and allowances, but not in rank, to and including the pay and allowances of captain, subject to such examinations as the Secretary of the Navy may prescribe, except that the number of dental surgeons with the pay and allowances of captain shall not exceed four and one-half per centum and the number of dental surgeons with the pay and allowances of commander shall not exceed eight per centum of the total authorized number of dental officers: *Provided further*, That dental surgeons shall be eligible for advancement to the pay and allowances of commander and captain when their total active service as dental officers in the Navy is such that if rendered as officers of the Naval Medical Corps it would place them in the list of medical officers with the rank, pay, and allowances of commander or captain, as the case may be: *And provided further*, That dental officers who shall have gained or lost numbers on the Navy list shall be considered to have gained or lost service accordingly; and the time served by dental officers on active duty as acting assistant dental surgeons and assistant dental surgeons under provisions of law existing prior to the passage of this Act shall be reckoned in computing the increased service pay and service for promotion of dental officers herein authorized or heretofore appointed.

All appointees authorized by this Act shall be citizens of the United States between twenty-one and thirty-two years of age, and shall be graduates of standard medical or

dental colleges and trained in the several branches of dentistry, and shall, before appointment, have successfully passed mental, moral, physical, and professional examinations before medical and professional examining boards appointed by the Secretary of the Navy, and have been recommended for appointment by such boards: *Provided*, That hereafter no person shall be appointed as assistant surgeon in the Navy who is not a graduate of a standard medical college.

Officers of the Naval Dental Corps shall become eligible for retirement in the same manner and under the same conditions as now prescribed by law for officers of the Naval Medical Corps, except that section 1445 of the Revised Statutes of the United States shall not be applicable to dental officers, and they shall not be entitled to rank above lieutenant commander on the retired list, or to retired pay above that of captain.

All dental officers now serving under probationary appointments shall become immediately eligible for permanent appointment under the provisions of this Act, subject to the examinations prescribed by the Secretary of the Navy for original appointment as dental surgeon, and may be appointed assistant dental surgeon with the rank of lieutenant (junior grade) to rank from the date of their probationary appointments: *Provided*, That the senior dental officer now at the United States Naval Academy shall not be displaced by the provisions of this Act, and he shall hereafter have the grade of passed assistant dental surgeon and the rank, pay, and allowances of lieutenant, and he shall not be eligible for retirement before he has reached the age of seventy years, except for physical disability incurred in the line of duty: *Provided further*, That no dental officer in the Navy who on original appointment as dental officer was over forty years of age, shall be eligible for retirement before he has reached the age of seventy years, except for physical disability incurred in line of duty.

All Acts or parts of Acts inconsistent with the provisions of this Act are hereby repealed: *Provided*, That nothing herein shall be construed to reduce the rank, pay, or allowances now authorized by law for any officer of the Navy.

ARMY AND NAVY DENTAL NEWS

Medical Department Training.

DENTAL OFFICERS.

THE first class of dental officers to be sent to the medical officers' training camp at Fort Oglethorpe, Ga., will commence the course of instruction on March 15th. The course will last for two months. During the first month about 180 hours will be devoted to general military subjects, and during the second month about 71 hours to these subjects and 100 hours to special dental subjects. The military staff already at the training camp will conduct the military instruction. Lieut.-Col. John H. Snapp, dental corps, has been relieved from duty at Camp Upton, N. Y., and assigned to duty as senior dental instructor at Fort Oglethorpe. He will be assisted by several members of the dental corps and by a staff of members of the dental reserve corps who have had experience, before entering the military service, as special instructors at dental colleges. It is planned to send to the camp each month a class of about eighty-five dentists, of whom all that can be spared from their present duties will be recent appointees to the dental corps, with a sufficient number from the dental reserve corps to make up the prescribed number. Preparations are being made for erection of special buildings for use in conducting the instruction in dental subjects. Plans for a general enlargement of the scope of training various classes of the *personnel* of the medical department at Fort Oglethorpe are awaiting approval. Besides the dentists, commissioned and enlisted members of the sanitary corps and veterinary corps also are to be put through special courses of instruction pertaining to their special work, some members of the sanitary corps already having been sent there. At present there are about 1500 officers and 9000 enlisted men of the medical department at the camp. A similar camp has been conducted at Fort Riley, Kans., where there are about 1000 officers and 6500 enlisted men. While it is not intended to

discontinue the Fort Riley establishment immediately, the plans that are being made contemplate a gradual enlargement of the facilities and scope of work at Fort Oglethorpe, to the end that the educational system of the Medical department, so far as it may be conducted at a training camp, eventually will be concentrated at that place, with a corresponding diminution at other places.

PLANS continue in course of development for increasing the size and scope of the establishment at Fort Oglethorpe, Ga., for the training of different classes of *personnel* of the Medical department, with a view to the ultimate concentration at that place of so much of the medical and allied educational system as may be conducted at a training camp. Brigadier-gen. Henry P. Birmingham, medical corps, national army, has been assigned to command the camp. He has been relieved from duty at Washington in the office of the Surgeon-general of the army and ordered to proceed to Fort Riley, Kans., for the purpose of inspecting the medical officers' training camp at that post and then to proceed to Fort Oglethorpe for station. Besides training of medical officers, training also will be given to members of the dental corps, dental reserve corps, sanitary corps, and veterinary corps. The first class of dentists, made up of fifty members of the regular corps and thirty-five members of the reserve corps, commenced the two months' course of instruction on March 15th. Lieut.-col. John H. Snapp, dental corps, is the senior dental instructor, and he is assisted by Majors Ben H. Sherrard and E. Henry Valentine, of the dental corps, and Major John D. Eby, of the dental reserve corps. Among the new schools to be established at Fort Oglethorpe is one for the physical diagnosis of lung diseases, with Captains William N. Anderson, Henry C. Drew, and James W. Price, medical reserve corps, as instructors.—*Army and Navy Register*.

Medical Corps Commissions.

SOMETHING of a muddle has resulted from conflicting decisions regarding the authorized enlisted strength of the regular army as a basis for determining the number of officers allowed the Medical corps and Dental corps, Sect. 10 of the National Defense Act of June 3, 1916, providing that—"The total number of such officers shall approximately be equal to, but not exceed, except as hereinafter provided, seven for every one thousand of the total enlisted strength of the regular army authorized from time to time by law;" and also authorizing the appointment of dental surgeons "at the rate of one for each one thousand enlisted men of the line of the army."

By one decision a strength of approximately 300,000 was used as a basis for determining the allowance of officers of the medical corps; the numbers in the several grades were adjusted on this basis, and some officers were nominated, confirmed, and commissioned in higher grades on this basis. It was claimed in behalf of the medical officers that the temporary strength prescribed from time to time for the signal corps in accordance with the Aviation Act of July 24, 1917, should be included in computing the strength of the regular army for determining the allowance of officers of the medical corps, and that a strength of approximately 450,000 should be used at this time as a basis.

The matter was reconsidered by the Judge Advocate-general of the army and by the general staff, and now it has been decided that the temporary strength of the signal corps and some other factors proposed by the Surgeon-general's office should not be included, and that the number of officers of the medical corps should be determined on a basis of about 213,000 enlisted men. With a computation of the allowance on the latter basis, it is found that the number of medical officers commissioned in higher grades exceeds the allowance.

It becomes at once a question as to what may be done in the cases of these excess officers. Their commissions having been issued after confirmation by the Senate, they cannot now be recalled, and naturally the officers affected are reluctant to surrender them. So far as it has been determined, it probably will be necessary to carry them in these grades as supernumeraries, to be absorbed later as vacancies occur. While the decision does not affect the dental officers to such an extent as the medical officers, for

the reason that it is prescribed that their numbers shall be based on the number of enlisted men in the "line" of the army, it does affect indirectly a determination of their allowance, but so far no excess commissions in higher grades have been issued.—*Army and Navy Register*.

Medical Students Commissioned.

UNDER a recent arrangement between the Navy and War departments, the privilege has been extended to enrolled medical and dental students to accept commissions in the medical corps of either branch of the service. The privilege applies to either the army or the navy; that is, an enrolled medical student of the naval reserve force may accept a commission in the medical reserve corps of the army, and *vice versa*. To be relieved, however, of his obligation as an enrolled enlisted man, he must accept active duty, for no enrolled students will be disenrolled in order to accept a commission in the inactive reserve in the other branch of the service. The operations of the selective draft law had the effect of greatly increasing the number of enrolments of medical and dental students, particularly in the naval reserve force. These men will be permitted to pursue their course of instruction until they graduate, when they will probably be called to active duty and instruction in hospitals and at training stations. It is not expected that undergraduates will be assigned to active duty during their vacation period.—*Army and Navy Register*.

Navy's Call for Binoculars, Spy Glasses and Telescopes.

"THE EYES OF THE NAVY."

MR. Franklin D. Roosevelt, assistant secretary of the navy, announces that the navy is still in urgent need of binoculars, spy glasses, and telescopes. The use of the submarine has so changed naval warfare that more "eyes" are needed on every ship, in order that a constant and efficient lookout may be maintained. Sextants and chronometers are also urgently required.

Henceforth, the United States has been obliged to rely almost entirely on foreign countries for its supply of such articles. These channels of supply are now closed, and as no stock is on hand in this country to meet the present emergency, it has become necessary to appeal to the patriotism of private owners to furnish "eyes for the navy."

Several weeks ago, an appeal was made through the daily press, resulting in the receipt of over 3000 glasses of various kinds, the great majority of which have proved satisfactory for naval use. This number, however, is wholly insufficient, and the navy needs many thousands more. He therefore asks that subscribers give special attention to this call.

All articles should be securely tagged, giving the name and address of the donor, and forwarded by mail or express to the Hon. Franklin D. Roosevelt, assistant secretary of the navy, care of Naval Observatory, Washington, D. C., so that they may be acknowledged by him.

Articles not suitable for naval use will be returned to the sender. Those accepted will be keyed, so that the name and address of the donor will be permanently recorded at the Navy Department, and every effort will be made to return them, with added historical interest, at the termination of the war. It is of course impossible to guarantee them against damage or loss.

As the Government cannot, under the law, accept services or material without making some payment therefor, one dollar will be paid for each article accepted, which sum will constitute the rental price, or in the event of loss, the purchase price, of such article.

Navy Needs No More Dental Students.

ENROLMENTS of dental students in the Naval Hospital Corps Reserve have been suspended, a sufficient number of embryo dentists having been obtained to meet the navy's needs for the present. About three hundred students of this class were enrolled. Enrolments of medical students will continue indefinitely, under the same conditions as enrolments have been conducted for the reserve during the past few months. The regular hospital corps of the navy is filled to its legal capacity, but with the increase in the enlisted *personnel* which has been recommended by Secretary Daniels, there will be an automatic increase in the complement of the hospital corps, bringing the strength up to over 9000, and active enlistments will be resumed. The hospital corps has proved very popular since the legislation of 1916 putting the corps on the same basis as other branches of the navy, and transfers in increasing numbers are being made from other branches of the navy and of the marine corps.—*Army and Navy Register*.

Army Dental Corps.

It was expected there would be about 250 vacancies to be filled in the Army Dental Corps, but in view of the new ruling as to enlisted strength of the army, upon which the *personnel* of the dental corps is based, the actual vacancies have been reduced to two. There were 211 in the dental corps, which is entitled to 212, and recently one officer was retired for physical disability. With a knowledge of but two vacancies existing, it is not expected that many of the 375 candidates who were invited to appear before examining boards on March 11th really presented themselves.—*Army and Navy Register*.

NEW APPOINTMENTS—ARMY DENTAL CORPS.

To be DENTAL SURGEONS with the rank of lieutenant (junior grade) for a probationary period from October 16th: W. T. Davidson, H. A. Badger, P. F. Kennedy, Canute Hansen, H. A. Sturtevant, L. E. McGourty, S. O. Claytor, J. McK. Campbell, J. W. Ridgway, Hyman Mann, Hubert Lehman, J. A. Walsh, W. E. Coverley, and W. A. Dorney.

The following from November 1st: D. L. Cohen and E. B. Faxon.

The following from February 9th: H. R. McCleery, A. T. Fellows, G. A. Collins, F. A. Zastrow and J. F. McGrath.

ADVANCEMENT IN RANK—DENTAL RESERVE CORPS. (March 2d.)

The promotion of the following-named first lieutenants is announced:

To be MAJORS: Archibald L. Miller, Albert Mehrer, Walter H. Richardson, Grove W. Dunham, Sherman M. Fowler, Donald D. Cornell, Ernest O. Lawing, and John Voss.

To be CAPTAINS: 1st Lieuts. Edwin H. Smith, Charles W. Swing, Philip H. Woods, Walter E. Lotz, Wm. G. Buchanan, Wm. W. Peebles, James E. Johnson, Thereon J. Hickey, George A. Withrow, James T. Cannon, Walter LeR. Wilson, Victor I. Buss, Floyd E. West, Wm. R. Cashin, Arthur A. Hoffman, Albert W. Anderson, Wm. E. Boyle, Edgar T. Blocher, George H. Elliott, Charles H. Masters, Charles A. McDermand, Frank R. Woods, James W. Ferguson, DeWilton H. Milstead, Jesse J. Corlew, John F. Clark, Edward F. Lafitte, Edwin C. Baker, Louis A. Haffner, Louis H. Caderette, Joseph A. Corriveau, George V. Cannon, Wm. M. Bergan, Irving P. Carr, James E. Cox, George N. Abbott, David S. Bedrick, Wilbur A. Charron, Wm. L. Davidson, Wm. P. Delafield, Wm. A. Walzem, Milton H. Anderson, Walter Sorenson, Charles J. Meyer, Thomas J. Guilfoil, James

H. Keith, Walter Grandage, Thomas E. Power, Frederick W. Day, Wm. B. Cobb, John J. Lally, Frank L. Hardy, Wm. R. Beattie, Sperry B. Claypool, Roy A. Stout, Albert E. Thornberry, Shubael C. Stratton, Albert W. Farley, Warren E. Guerrier, Cornelius Locke, Harrison B. Wall, Clarence P. Landgrebe, Oakley B. Davy, Max C. Frazier, Charles F. Huber, Claude L. Hunsicker, James W. McGuire, Thomas L. Rice, and Stanton L. Sherman.

To be MAJORS (March 9th): 1st Lieuts. Joseph D. Eby, Oscar LeRoy Whitson, Ernest Eugene Buell, Harry Paulus Bachman, and Wilbert J. Scruton.

To be CAPTAINS (March 9th): Daniel T. Bowers, David G. Everhart, Melvin M. Augenstein, Wm. O. Boss, Fred Tiesse, Jr., John C. McElhaney, Wm. B. Noble, Denzil C. Barnhill, Ernest E. Boyd, Albert L. Bruener, Walter T. Clark, and Gordon L. Ross.

To be MAJORS (March 16th): 1st Lieuts. Joseph A. Boarts and John McD. Eveleth.

Assignments.

Army Dental Corps.

Week ending February 16th.

1st Lieut. Glover Johns from duty at Camp MacArthur, Tex., to Fort Sam Houston for duty.

1st Lieut. Joseph E. Schaefer from duty at Camp Meade, Md., to Surgeon-general's office for temporary duty.

The following to Philadelphia, School of Plastic and Oral Surgery, Evans Dental Institute, for instruction and return to proper station: 1st Lieuts. Wm. J. R. Akeroyd, Frederick C. Daniels, and Julius L. Bischof.

The following upon arrival in United States to Washington for examination for promotion: Majors Charles C. Mann and Arthur J. Skillman; and Major Mann to Columbus

Barracks for duty, and Major Skillman to Camp Upton, N. Y., 77th division, for duty.

Week ending February 23d.

Major Arthur J. Skillman to Chillicothe, Ohio, Camp Sherman, for duty.

Week ending March 2d.

Lieut. Col. John H. Snapp from duty at Camp Upton, N. Y., to Fort Oglethorpe, medical officers' training camp, for duty as senior dental instructor.

Week ending March 9th.

Leave for three months on surgeon's certificate granted Lieut.-col. Raymond E. Ingalls.

Week ending March 16th.

Lieut.-col. George E. Stallman (promoted subject to examination), having been examined for promotion and found physically disqualified for duties of lieut.-col. in dental corps by reason of disability incident to service, his retirement as a lieut.-col. is announced. He will proceed to his home.

Major Arthur J. Skillman to Camp Sherman, Ohio, for duty in base hospital.

1st Lieut. Julius L. Bischof from Evans Dental Institute, Philadelphia, to Camp Joseph E. Johnston, Fla., for temporary duty in base hospital.

The following to Fort Oglethorpe, medical officers' training camp, for duty: 1st Lieuts. Wm. F. Scheumann and John N. White.

The following to Fort Oglethorpe, medical officers' training camp, for course of instruction: 1st Lieuts. Harold A. Curtis, Lawrence J. Dunn, Carl R. Oman, John L. Richards, Thomas H. Veale, and Carl S. Emmer.

Dental Reserve Corps.

Week ending March 9th.

Capt. Cornelius Locke to Panama Canal Department for duty.

Preparedness League of American Dentists.

(Organized under the auspices of the N. D. A.)

The Dental Committee of the General Medical Board, which is the agency for the Medical and Dental Preparedness in this War-emergency has made it possible for every Dentist in the United States to assist in the work, under the supervision of
Lieut. WM. A. HECKARD, D.R.C., U.S.A., stationed at
50 East 42d st., New York, N. Y.

Preparedness League Notes and News.

By R. OTTOLENGUI, *Publicity Committee.*

REPORT FROM THE PRESIDENT.

The Preparedness League of American Dentists has now become the recognized medium for carrying on the work relative to the preparation of our men for service prior to their entrance to training camps. It is with pride and a sense of deep satisfaction that I refer to the splendid organization of the League in this particular department of our activities, and I sincerely commend the efforts of those who have given material assistance in bringing about this situation. A development deemed most advisable was the appointment of a director of publicity, to which office Dr. R. Ottolengui was duly elected. I will not anticipate his plan of procedure, but wish merely to assure our members of our satisfaction in his election, and confidence in the results to be obtained through this medium.

The present month of March is the second anniversary of the formation of the League, and indicates the advantage gained by early organization for the promotion of the great work it has undertaken. Our work had continued for a period of fourteen months prior to the declaration of war, and when the word came, the machinery for utilizing the services of our profession was practically completed and oiled ready for use.

We are pleased to announce the *personnel* of the officers of the League elected at our last regular meeting: J. W. Beach, president; O. U. King, Chicago, vice-president; H. C. Brown, Columbus, secretary; L. M. Waugh, New York, treasurer; Lieut. W. A. Heckard, New York, honorary executive secretary, and Chas. F. Ash, New York, director-general. J. Lowe Young and Leland Barrett are members of the Finance Committee, and the subcommittee on Preparedness League of American Dentists, Committee on Dentistry, Council of National Defense, consists of J. W.

Beach, chairman; J. A. C. Hoggan, Chas. F. Ash, W. D. Tracy, F. M. Casto, D. M. Gallie, M. B. Eshleman, L. L. Barber.

J. W. BEACH, *President.*

REPORT FROM THE DIRECTOR-GENERAL.

We are receiving many letters in which the writer says he has sent in his dollar but has not received his button. Owing to the large number of applications received, running into the thousands, it requires considerable time to tabulate their names and get out the acknowledgments; also there are not enough buttons on hand, and more have been ordered. We ask indulgence in this matter.

I am inclosing also herewith the list of states showing the order in which the printed matter has been mailed. This list will show the extent to which we have endeavored to get into working order the details of the system so as to make it as easy as possible for our directors in the various states. In this way the director the farthest removed will receive his materials and supplies about the same time they are delivered to the nearby states: Porto Rico, Alaska, California, Washington, Oregon, Montana, Idaho, Wyoming, Nevada, Utah, Colorado, Arizona, New Mexico, Texas, Missouri, Iowa, Kansas, Nebraska, North Dakota, South Dakota, Minnesota, Wisconsin, Illinois, Arkansas, Oklahoma, Florida, Alabama, Georgia, South Carolina, North Carolina, Louisiana, Mississippi, Tennessee, Indiana, Kentucky, Michigan, West Virginia, Ohio, Virginia, District of Columbia, Maryland, Delaware, Maine, New Hampshire, Vermont, Massachusetts, Pennsylvania, Rhode Island, Connecticut, New Jersey, New York.

CHAS. F. ASH, *Director-general.*

REPORT FROM THE TREASURER.

When we started the recent drive for new members we had 5700 members. On March

1st the total of new members received during January and February amounted to 6707, making a grand total of 12,407.

L. M. WAUGH, *Treasurer*.

REPORTS FROM DIRECTORS OF DEPARTMENTS.

WESTERN DEPARTMENT.

Besides the draft work, which is progressing favorably in this department, we are endeavoring to provide a school of instruction for all dental reserve officers not on duty. In California such a school is to be held at the Dental Department of the University of California and at the Dental Department of the University of Southern California, where it is proposed to have regular dental officers instructing in army regulations, etc. This course will be one week, is open to all dental officers holding commissions, and is free of any cost.

We hope by this method to have the different officers under observation long enough so that we will be able to recommend those qualifying the highest for active duty, and in this way raise the efficiency of the dental corps.

It is thought that this is work for the Preparedness League, as it really prepares the dental officers for their future duties.

Arrangements are being made to have all dental societies located near training camps assist the training camp dental societies with their programs.

JOHN D. MILLIKEN, *Director Western Dept.*

SOUTHERN DEPARTMENT.

The idea of reaching the profession through the dental journals is certainly a good one, but to my mind it does not go far enough. The dire need of this work is publicity that reaches the layman, not the dentist. We have lacked the co-operation of state officials through ignorance of our work. We have had half-hearted response from many dentists who I am sure would jump into the collar if the general public knew of the work. This may not be patriotism, but it is certainly psychology.

I wrote Dr. Ash some time ago about this proposition, asking if there were not some way in which we could advertise this work to the public without mentioning names. I believe if personality creeps into the advertising it will do more harm than good. I offer this merely as a suggestion, and will be glad to have your views in the matter.

W. D. McCARTY, *Director Southern Dept.*

REPORT OF DIRECTOR OF PUBLICITY.

Dr. W. D. McCarty very well epitomizes the requirements of publicity. I agree with him that publicity through the dental journals will be advantageous, but the publicity that will reach the public will serve us even better. I therefore solicit aid in both directions.

PUBLICITY THROUGH DENTAL JOURNALS.

To thoroughly make use of this medium, the officers and directors should comprehend the method of dissemination and its limitations. All dental journals aim to appear on the first of each month. To accomplish this all copy must be in the hands of the editors by the 10th of the previous month. Some of the journals are nearly five days away from New York by mail. Hence I must have a copy in my hands by the first of each month. It is then arranged, sent to the printer, put into type, and galley proof-sheets mailed to all the dental journals, that the editors may use as much thereof as they may have space for. Thus all matter appearing in the dental journals is at least a month old when put into print. This should be taken into consideration when read. It should likewise be considered when preparing matter for transmission to me. It is difficult to state in advance just what sort of information is desirable. The officers and directors are requested to forward matter with the following basic ends in view: (1) The increase of interest in League work by the dental profession; (2) increase in membership; (3) increase in efficiency. In regard to efficiency, while suggestions are always in order, it should be remembered that the plan that fits the largest number of localities is the best plan. Therefore if the plan that is satisfactory to the majority does not exactly suit you, Mr. Director, adopt it anyway. Alter your own views, rather than the plan. There can be but one plan.

MEDICAL ADVISORY BOARD WORK.

During February a meeting was called of the fifty dentists assigned to medical advisory boards in New York City, and an organization was perfected under the name, "The Dental Committee of the New York Medical Advisory Boards." By this meeting a more co-ordinate plan of procedure was perfected. By the time of the next big draft we hope to have dentists on all the local exemption boards. As soon as these men have been appointed, a joint meeting of the medical board dentists and the local board dentists will be called,

and the new men will receive the benefit of advice born of experience. It was a satisfaction at the first meeting of the Dental Committee of the New York Medical Advisory Boards to find that everyone was already a member of the League.

LOCAL EXEMPTION BOARDS.

As the local exemption boards will select the majority of the men accepted for active duty, and as these are exactly the men for whom the League desires to work, it is manifest that as quickly as possible we should have dentists on all exemption boards through-

out the country. This has already been accomplished in several states, and strenuous efforts are being made to have such appointments made in all states. Therefore, to facilitate progress, it would be well for every state director to begin at once making out lists of men who would volunteer for this patriotic duty. It perhaps would be best to ask the presidents of local societies to select these men. Do it now! Then when the Government announces that appointments to your local boards will be made, and asks for a list of men, you can forward your list by return mail. That would be impressive! That would be efficiency!

SPECIAL NOTICE.

Dental Library Association.

BELIEVING that one of the most important functions of a dental library is the interchange and exchange of dental books and journals, it has been thought advisable by a great many dental librarians to form a DENTAL LIBRARY ASSOCIATION, similar to the Medical Library Association.

OBJECT.

The fostering of dental libraries and the maintenance of a system for exchange of dental literature and duplicates; securing and distributing the Transactions of dental societies.

ELIGIBLE FOR MEMBERSHIP.

Any dental society, association, university, college, or library having a fixed home and a dental library; any individual interested in dental literature or libraries.

BENEFITS.

The banding together of a united body, with a common cause; the betterment of conditions in dental libraries; a clearing-house through which books, journals, reprints, or lists of these, may be sent from one library to another.

We desire to know what libraries now exist, and how many would be interested in the formation of such a society.

The undersigned may be addressed as Librarian First District Dental Society, at N. Y. Academy of Medicine, 17 W. 43d st., New York City, or as below.

DR. B. W. WEINBERGER,
40 E. 41st st., New York City.

SOCIETY NOTES AND ANNOUNCEMENTS

NOTICES should reach the Office of the DENTAL COSMOS not later than the 11th or 12th of the month preceding that of publication.

Coming Dental Society Meetings.

National.

NATIONAL DENTAL ASSOCIATION. Chicago. August 5th to 9th.

NATIONAL ASSOCIATION OF DENTAL FACULTIES. Chicago. August 2d and 3d.

NATIONAL ASSOCIATION OF DENTAL EXAMINERS. Chicago.

NORTH CAROLINA BOARD OF EXAMINERS. Wilmington. June 17th.

PENNSYLVANIA BOARD OF EXAMINERS. Philadelphia and Pittsburgh. June 12th to 15th.

SOUTH CAROLINA BOARD OF EXAMINERS. Columbia. June 24th.

National Association of Dental Faculties.

THE next annual meeting of the National Association of Dental Faculties will be held in the Green room of the Congress Hotel, Chicago, Ill., August 2, 1918, at noon. The Executive Committee will meet at 10 A.M. on the 2d. The meeting will continue through August 3d.

CHAS. C. ALLEN, *Sec'y*,

N. W. cor. 10th and Troost, Kansas City, Mo.

American Society of Orthodontists.

THE eighteenth annual meeting of the American Society of Orthodontists will be held August 1, 2, and 3, 1918, at the Edgewater Beach Hotel, Chicago, Ill.

This will be an excellent meeting. It is advisable to make your reservations early.

F. M. CASTO, *Sec'y*,

Rose Bldg., Cleveland, Ohio.

Baltimore College of Dental Surgery.

CLASS OF 1913.

WILL the members of the above class kindly communicate to the president of the class their present address?—that he may write

them in reference to class reunion to be held in the near future, *i.e.* May or June; also expressing opinion as to their preference of date.

A. L. CAIRNS,

1378 Beacon st., Brookline, Mass.

H. W. DOREMUS,

Orange and Seventh sts., Newark, N. J.

Pennsylvania State Dental Society.

THE golden anniversary meeting of the Pennsylvania State Dental Society will be held in Wilkes-Barre, April 23, 24, 25, and 26, 1918. Excellent talent has been secured for the occasion and the program extended to a four days' session. To judge by preliminary reports of committees, this event promises to be the greatest meeting in the history of this organization. All ethical practitioners are cordially invited to attend.

J. F. BIDDLE, *Sec'y*,

517 Arch st., Pittsburgh, Pa.

Texas State Dental Society.

THE thirty-eighth annual convention of the Texas State Dental Society will be held at San Antonio, Texas, the famous City of the Alamo, April 10, 11, and 12, 1918. Members of other state societies are cordially invited to attend.

J. G. FIFE, *Sec'y*,

736 Wilson Bldg., Dallas, Texas.

Mississippi State Dental Association.

THE forty-third annual meeting of the Mississippi State Dental Association will occur in Meridian, April 16, 17, and 18, 1918, at which time the officers of the society unite with the Meridian members in promising a most instructive and enjoyable meeting.

W. C. DENNIS, *Sec'y*,

Jackson, Miss.

Michigan State Dental Society.

THE sixty-second annual meeting of the Michigan State Dental Society will be held at the Hotel Statler, Detroit, Mich., the week of April 8 to 13, 1918. The regular meeting will be held on April 8th and 9th, with a splendid program. The remainder of the week will be a postgraduate meeting, in charge of the Detroit Club Clinic, at which every important branch of dentistry will be covered.

C. G. BATES, *Sec'y*,

Durand, Mich.

Odontological Society of Western Pennsylvania.

THE thirty-seventh annual meeting of the Odontological Society of Western Pennsylvania will be held in the Hotel Chatham, Penn ave. and Fourth st., Pittsburgh, Pa., Tuesday and Wednesday, April 9 and 10, 1918.

The Program Committee promises one of the best dental meetings ever held. Men of note will read papers of interest to the twentieth-century dentist.

The clinics will be given by the study clubs of Western Pennsylvania, and will be of interest to all.

Exhibitors will be amply accommodated with space by addressing Dr. Leslie Waddill, Jenkins Arcade Bldg., Pittsburgh, Pa.

KING S. PERRY, *Sec'y*,
719 Jenkins Bldg., Pittsburgh, Pa.

Virginia State Dental Association.

CHANGE OF DATE OF MEETING.

THE Virginia State Dental Association will meet in Roanoke, Va., April 29 and 30, and May 1, 1918.

F. R. TALLEY, *Corr. Sec'y*,
Petersburg, Va.

Connecticut Dental Hygienists' Association.

THE fourth annual convention of the Connecticut Dental Hygienists' Association will be held at the Taft Hotel, New Haven, Friday and Saturday, April 19 and 20, 1918.

On Friday evening a joint meeting of the Connecticut State Dental Association and the Connecticut Dental Hygienists' Association will be held, with Dr. Weston A. Price as the speaker.

Saturday morning interesting papers will be read, and on Saturday afternoon twenty dental hygienists will demonstrate various phases of their work, such as that of the dental clinic in the public schools of Bridgeport, a progressive clinic showing the technique of instrumentation, polishing, brushing, use of mouthwash and dentifrice, a dental hygienist in hospital work, and also a demonstration of the technique in taking radiographs.

All who are interested in mouth hygiene are welcome.

ROSE E. HOUSE, *Sec'y*,
705 Wood ave., Bridgeport, Conn.

Missouri State Dental Association.

THE fifty-third annual meeting of the Missouri State Dental Association will be held at Columbia, Mo., April 1, 2, and 3, 1918. A splendid program is in preparation, and great things may be expected.

J. F. WALLACE, *Sec'y*,
Canton, Mo.

Kansas State Dental Association.

THE annual meeting of the Kansas State Dental Association will be at Topeka, Kans., on April 15, 16, and 17, 1918.

C. K. WEAVER, *Sec'y*,
Clay Center, Kans.

Connecticut State Dental Association.

THE fifty-fourth annual meeting of the Connecticut State Dental Association will be held at the Hotel Taft, New Haven, Conn., April 18, 19, and 20, 1918.

GEO. S. B. LEONARD, *Sec'y*.

Ontario Dental Society.

THE fifty-first annual meeting of the Ontario Dental Society will be held in Toronto, Canada, April 29th to May 2d.

J. P. MACLACHLAN, *Sec'y*,
26 College st., Toronto, Can.

Iowa State Dental Society.

THE fifty-sixth annual meeting of the Iowa State Dental Society will be held in Des Moines, Iowa, May 7, 8, and 9, 1918. An excellent program has been prepared, including seminars, papers, and clinics. A cordial invitation is extended ethical members of the profession from out of the state to attend any or all of these sessions.

E. R. SWANK, *Sec'y*,
Panora, Iowa.

Massachusetts Dental Society.

THE fifty-fourth annual meeting of the Massachusetts Dental Society will be held in Boston, Mass., on Wednesday, Thursday, and Friday, May 1, 2, and 3, 1918, at the Massachusetts Charitable Mechanic Association Building on Huntington ave.

WALDO E. BOARDMAN,
Ch'man Ex. Com.

J. ARTHUR FURBISH, *Sec'y*,
400 Marlboro st., Boston, Mass.

Eastern Association of Graduates of the Angle School.

THE annual meeting of the Eastern Association of Graduates of the Angle School of Orthodontia will be held at the Hotel Vanderbilt, New York City, on Monday and Tuesday, May 6 and 7, 1918.

FREDERIC T. MURLESS, JR., *President*,
Hartford, Conn.

E. SANTLEY BUTLER, *Sec'y*,
576 Fifth ave., New York City.

Illinois State Dental Society.

THE fifty-fourth annual meeting of the Illinois State Dental Society will be held at Bloomington, Ill., May 14, 15, 16, and 17, 1918.

J. E. HINKINS, *President*,
Chicago, Ill.

J. P. LUTHRINGER, *Sec'y*,
Peoria, Ill.

South Carolina State Dental Association.

THE annual meeting of the South Carolina State Dental Association will be held at the Jefferson Hotel, Columbia, S. C., June 27, 28, and 29, 1918.

W. BUSEY SIMMONS, *President*.
ERNEST C. DYE, *Sec'y*.

Kentucky State Dental Association.

THE next annual meeting of the Kentucky State Dental Association will be held at Lexington, Ky., June 13, 14, and 15, 1918. An "amalgam program" of special interest.

Address all correspondence to

W. M. RANDALL, *Sec'y*,
1035 Second st., Louisville, Ky.

Northwestern University Dental School.

ALUMNI ASSOCIATION CLINIC.

THE Northwestern University Dental School Alumni Association will hold the annual Home-coming Clinic, 31 W. Lake st., Chicago, Ill., on June 10 and 11, 1918. Special features have been provided which will insure a successful and interesting meeting. Make your arrangements now to be in attendance. For information address

M. M. PRINTZ, *Sec'y*,
4235 Lake Park ave., Chicago.

Dental Society of the State of New York.

THE fiftieth anniversary of the Dental Society of the State of New York will be held at Saratoga Springs, N. Y., June 13, 14, and 15, 1918. The society will endeavor to present a literary, clinic, and social program for the benefit of the profession, in keeping with its golden anniversary. A cordial invitation is extended to all members of the National Dental Association. For further information write

A. P. BURKHART, *Sec'y*,
52 Genesee st., Auburn, N. Y.

Northern Ohio Dental Association.

THE annual meeting of the Northern Ohio Dental Association will be held June 6, 7, and 8, 1918, at Toledo, Ohio.

C. H. CLARK, *Sec'y*,
Youngstown, Ohio.

Georgia State Dental Society.

THE semi-centennial meeting of the Georgia State Dental Society will be held in Atlanta, Ga., June 12, 13, and 14, 1918, when this society will celebrate its fiftieth anniversary.

North Carolina Dental Society.

THE North Carolina Dental Society will meet on June 19 to 21, 1918. Headquarters, Oceanic Hotel, Wilmington, N. C.

W. T. MARTIN, *Sec'y*.

Tennessee State Dental Association.

THE fifty-first annual meeting of the Tennessee State Dental Association will be held in Nashville, Tenn., June 17, 18, and 19, 1918.

GEO. L. POWERS, *Sec'y*,
Paris, Tenn.

Florida State Dental Society.

THE Florida State Dental Society will hold its next annual meeting at the Atlantic Beach Hotel, Atlantic Beach, Fla., on June 20, 21, and 22, 1918, where fishing, golfing, and surf bathing is unsurpassed.

A fine program is being planned. All ethical practitioners of this and other states invited.

For further particulars address

D. D. CREWS, *Sec'y*,
Fort Myers, Fla.

Postgraduate Dental Meeting:

Alabama—Mississippi—Texas—
Louisiana.

BECAUSE of the great success of last year's "Four States Postgraduate Dental Meeting" from an educational standpoint, the president of the Louisiana State Dental Society called a special meeting to elect a committee to make arrangements for another postgraduate meeting this year. Committee elected follows:

General Chairman—J. J. Sarrazin, 424 Godchaux Bldg., New Orleans, chairman Committee on Interstate Relations.

General Secretary—Leo C. Dempsey, 943 Jackson ave., New Orleans.

S. H. McAfee, 1237 Maison Blanche, New Orleans, chairman Scientific Program Committee.

J. P. Wahl, 1135 Maison Blanche, New Orleans, Editor *Bulletin* and chairman Publicity Committee.

O. L. Loeffel, 727 Maison Blanche, New Orleans, chairman Committee Arrangements and Hotel Rates.

C. S. Tuller, 729 Maison Blanche, New Orleans, chairman Committee on Exhibits.

J. A. Gorman, 629 Maison Blanche, New Orleans, chairman Committee on Clinics.

C. V. Vignes, 709 Macheca Bldg., New Orleans, chairman Committee on Credentials and Registration.

E. B. Ducasse, 735 Maison Blanche, New Orleans, chairman Floor Committee.

A. L. Ducasse, 735 Maison Blanche, New Orleans, chairman Committee on Special Courses.

REGULATIONS.

(1) *Place of meeting.* New Orleans, at the Grunewald Hotel.

(2) *Date.* To avoid interfering with dental college exercises and dental examining board meetings, and to be assured of pleasant weather, June 3, 4, 5, and 6 was selected.

(3) In order to give each member an equal opportunity to get all that is possible and not congest the meeting, the membership will be limited to 350 members.

(4) Membership cards will be issued only to members in good standing in their state dental societies, and to dentists in the army and navy dental corps.

(5) The registration books will be closed May 27th (one week before the meeting) to all except members of the army and navy dental corps.

(6) *Fee.* Owing to increased cost of postage and stationery and all other expenses, the membership fee to the general meeting will be ten dollars for each member. Special

courses following the general meeting, fifteen dollars for each course per member.

(7) No one will be issued a special course card unless he has registered for the general meeting.

The subjects chosen to be taught at the next meeting will be as follows:

"Nerve Blocking." Dr. Arthur E. Smith, Chicago.

"Technique of Root-canal Preparation, Treatment, and Filling." Dr. Elmer S. Best, Minneapolis.

"Full Upper and Lower Dentures." Dr. Rupert E. Hall, Chicago.

"Exodontia." (Instructor to be selected.)

Ask yourself the question, Can I afford to miss this meeting? Send your application for membership to the Four States Postgraduate meeting, with your check for ten dollars, to your state chairman for indorsement and transmission by him to Dr. L. C. Dempsey, the general secretary. Members of the Louisiana State Dental Society can apply direct to Dr. Dempsey with membership fee inclosed.

Special Committee for Alabama: Chas. F. Chandler, chairman, 701 First National Bank Bldg., Montgomery; F. F. Perry, secretary, 502 First National Bank Bldg., Montgomery; J. A. Blue, treasurer, 502 Brown-Marx Bldg., Birmingham; Olin Kirkland, 913 Bell Bldg., Montgomery; C. B. Fowlkes, 812 City Bank Bldg., Mobile; W. F. McDaniels, Athens.

Special Committee for Texas: E. W. Smith, chairman, Dallas; Tom F. Coyle, Orange; P. C. Krupp, 905 Union National Bank Bldg., Houston; M. J. Bisco, American National Bank Bldg., Fort Worth; B. F. Thielen, 301 Scott Bldg., Paris, Texas.

Special Committee for Mississippi: M. B. Varnado, chairman, Osyka; W. C. Dennis, Jackson; C. B. Baker, Amory; A. B. Kelly, Yazoo City; J. N. Moffat, Shelby.

J. P. WAHL, *Ch'man Publicity Com.*

California State Dental Association.

THE California State Dental Association will hold its regular annual session for the year 1918 in San Francisco, July 8 to 13, 1918.

We will conduct our meeting this year on the Oklahoma plan, and feel that we can assure all who attend a pleasant as well as a profitable meeting. Further information may be obtained by addressing

JOHN E. GURLEY, *Sec'y*,
350 Post st., San Francisco.

Maine Dental Society.

THE fifty-third anniversary meeting of the Maine Dental Society will be held in the City-hall, Portland, Me., June 26 to 28, 1918.

I. E. PENDLETON, *Sec'y*,
Lewiston, Me.

New Jersey State Dental Society.

THE forty-eighth annual convention of the New Jersey State Dental Society will be held on July 17, 18, and 19, 1918, on Young's Million Dollar Pier, Atlantic City, N. J.

The entire convention will be held on the pier. Machinery Hall will be used for the exhibits. Those who attended last year will remember the magnificent display of dental goods, and Dr. S. I. Callahan of Woodstown, N. J., chairman of the Exhibit Committee, with 25,000 square feet of space, has promised an exhibit greater than that of 1917.

The Essay Committee under the direction of Dr. C. M. F. Egel of Westfield, will present two or three essayists of prominence—names and subjects to be announced.

All meetings for the presentation of papers as well as the business meetings will be held in the Greek Temple, out on the pier.

The headquarters of the society will be at the pier entrance. Mail may be directed to exhibitors, clinicians, or members in care of the Secretary New Jersey State Dental Society, Young's Million Dollar Pier.

A list of hotels where special rates may be secured will be published in the *New Jersey Dental Journal* prior to the convention, or may be secured by addressing the secretary.

A cordial invitation is extended to ethical practitioners.

JOHN C. FORSYTH, *Sec'y*,
430 E. State st., Trenton, N. J.

New Jersey Board of Registration.

THE State Board of Registration and Examination in Dentistry of New Jersey will hold their annual meeting and examination in the Assembly chamber, at the State-house, Trenton, N. J., on June 24, 25, 26, 27, and 28, 1918. License fee \$25, re-examination \$10.

Applications must be filed complete ten days before the date of the examinations. Address all communications for further particulars to

JOHN C. FORSYTH, *Sec'y*,
430 E. State st., Trenton, N. J.

Maryland Board of Examiners.

THE Maryland State Board of Dental Examiners will meet for examination of candidates for certificates in Baltimore, on May 30 and 31, 1918, at the Dental Department of the University of Maryland at 9 A.M.

For application blanks or further information apply to

F. F. DREW, *Sec'y*,
701 N. Howard st., Baltimore, Md.

Indiana Board of Examiners.

THE next meeting of the Indiana State Board of Dental Examiners will be held at the State-house, Indianapolis, June 17th to 22d inclusive. Applications and other information may be obtained by addressing

H. C. MCKITTRICK, *Sec'y*,
Indianapolis, Ind.

Pennsylvania Board of Examiners.

THE next examination of the Pennsylvania Board of Dental Examiners will be held in Philadelphia and Pittsburgh on Wednesday, Thursday, Friday, and Saturday, June 12th 13, 14, and 15, 1918.

The examination in practical work will be in the Evans Dental Institute, 40th and Spruce sts., Philadelphia, and the University of Pittsburgh, Pittsburgh, on Wednesday, June 12th. The examination in operative work will be held at 8.30 A.M. and the prosthetic work at 1.30 P.M. Applicants are required to furnish all instruments and a patient for the operative work.

The theoretical examination will be held in Musical Fund Hall, Philadelphia, and College of Pharmacy, Pride and Bluff sts., Pittsburgh, beginning at 9 A.M. on Thursday June 13th.

Application papers can be secured from the department of Public Instruction, Harrisburg.

ALEXANDER H. REYNOLDS, *Sec'y*,
4630 Chester ave., Philadelphia.

Michigan Board of Examiners.

THE next meeting of the Michigan State Board of Dental Examiners will be held at the Dental College, University of Michigan, Ann Arbor, Michigan, June 17 to 22 inclusive. Applications and other information may be obtained by addressing

B. S. SUTHERLAND, *Sec'y*,
Owosso, Mich.

North Carolina Board of Examiners.

THE next meeting of the North Carolina State Board of Dental Examiners will be held at Wrightsville Beach, Wilmington, N. C., beginning promptly at 9 o'clock on Monday morning, June 17, 1918. For further information and application blanks address

F. L. HUNT, *Sec'y*,
Asheville, N. C.

Mississippi Board of Examiners.

THE Mississippi Board of Dental Examiners will hold its next annual meeting at the State Capitol building in Jackson, on the third Tuesday in June 1918, at 8 A.M. Fee for examination \$10. Diploma from recognized school and certificate of moral character required. No reciprocity or interchange. For further information, address

B. J. MARSHALL, *Sec'y*,
Marks, Miss.

South Carolina Board of Examiners.

THE annual meeting of the South Carolina Board of Dental Examiners will be held at The Jefferson, Columbia, S. C., beginning promptly at 9 o'clock. Monday morning, June 24, 1918.

All applications must be in the hands of the secretary by June 14th. Application blanks and full information may be obtained by addressing

R. L. SPENCER, *Sec'y*,
Bennettsville, S. C.

Maine Board of Examiners.

THE Maine Board of Dental Examiners will hold their regular examination, beginning July 1, 1918, at 8.30 A.M., at the State-house.

All applications and fees, \$20, must be in the hands of the secretary by June 21, 1918.

The examination for DENTAL HYGIENISTS will be given at the same time; fee \$10.

WILL S. PAYSON, *Sec'y*,
Castine, Maine.

ORIGINAL COMMUNICATIONS

The Technique of Root Amputation.

By HERMANN PRINZ, D.D.S., M.D., Philadelphia, Pa.

From the Research Laboratories of the Evans Institute, Univ. Pennsylvania.

INTRODUCTION.

BY root amputation, root resection, or the more fanciful terms maxillotomy or apicoectomy, we understand the removal of more or less of the diseased root-end of a tooth and the involved periapical tissue by a surgical operation. This operation is by no means of recent origin. As early as 1871, J. S. Smith suggested it, and in 1880 Farrar described a detailed method of its application. Rhein, in 1890 and again in 1897, furnished suitable instructions regarding its technique, while Lodge in 1897 formulated the indications for its application. A systematic description of a satisfactory working method which has given most excellent results must be credited to Partsch. In 1896 and in subsequent publications he presented his operative procedures to the profession, and since then this method has been accepted as the operation of choice. During the last decade the literature on the subject has grown very voluminous, and

merely to recall a few of the more important contributors we enumerate the names of Blum, Dunn, Federspiel, Gilmer, Ivy, Lederer, Levy, Mayrhofer, McMillan, Naumann, Riesenfeld, Sausser, Schamberg, Thoma, Weiser, Williger, and others too numerous to mention.

INDICATIONS FOR THE OPERATION OF ROOT AMPUTATION.

It is quite impossible to specify an absolute indication for the operation of root amputation which holds good in every case. The correct diagnosis of the prevailing conditions in each individual case is the only definite indicator for the future therapeutic (surgical or medicinal) procedure. In general terms it may be stated that the following pathologic conditions—which, incidentally, constitute the so widely discussed vicious circle generically known at present as oral focal infection—render the operation of root resection justifiable: (1) Chronic alveolar abscesses, with or without fis-

tulas, which have defied medicinal treatment; (2) granulomas (chronic proliferating pericementitis); (3) radicular cysts; (4) deep fractures of roots; (5) hyperplasia of cementum (exostosis); (6) foreign bodies in root-canals, *i.e.* broken instruments, etc.

An imperative necessity for a correct diagnosis is a roentgenogram of the involved region. It should be understood, however, that the roentgen picture is primarily only an aid to the diagnosis; the basic principle of the latter involves a physical examination in all its aspects.

Regarding the suitability of the individual teeth for this operation, it may be stated that all the teeth with the exception of the third molars are amenable to it. Naturally, the single-rooted teeth offer the least difficulties; in multi-rooted teeth the operation is frequently materially simplified by excising the entire involved root.

Concerning the pathologic anatomy of the above enumerated classification, it may be not amiss to rehearse the more important facts involved in the various tissue changes. Acute apical pericementitis caused by infection, unless checked in time, results in a purulent osteitis, commonly referred to as alveolar abscess, while the chronic type, *i.e.* chronic proliferating pericementitis, manifests itself in the formation of an inflammatory fungoid new-growth, simple or epithelial granuloma. The dense wall of granulation tissue, in the past incorrectly referred to as the abscess sac or the pyogenic membrane, is intended by nature to protect the surrounding structures against infection from the root-canal. If the infection gets the upper hand, a subacute abscess is the sequence. The walls of the granuloma contain leucocytes, lymphocytes, plasma cells, droplets of fat, and a very rich blood supply. Infection of the granuloma usually is present only in about 30 per cent. of the cases; it may become infected at any time, however, as a sequence of renewed activity of the infected root-canal.

The epithelial granuloma is the most frequent type. Scattered in its wall are found the rests of the paradental epi-

thelial debris of Malassez, *i.e.* epithelial remnants of the embryonic dental groove or ridge. As a sequence of chronic irritation, principally from toxins, the epithelial rests begin to sprout and to grow until a complete sac is formed. At this moment the cyst is born, as it were.

Cysts may be defined as being sharply circumscribed collections of fluid confined to a cavity which has no channel of outflow. The cavity is lined with epithelium or endothelium. The dental cysts about the jaws, according to Magitot's classification, are divided into dentigerous and radicular cysts. It is only the latter type which interests us at this moment.

The growth of the cyst is unlimited; it is partially brought about by the increasing pressure of the accumulated fluid secreted by the epithelial lining, and partially, as Williger states, from mucoid degeneration of the connective tissue bundles encapsulated in the epithelial debris. The contents of the cyst consist of a more or less thick, viscid, glairy fluid, frequently containing crystals of cholesterol and occasionally calcareous deposits. At times the cystic fluid becomes infected and tinged with blood.

In a recent book on "Oral Abscesses," Thoma states that "The author agrees that cysts may be formed in both jaws from such conditions [granulomas], but this must happen extremely seldom, or we would meet with cysts more commonly in these days when granulomata are found in almost everybody's mouth." And in a discussion on this subject before a society meeting the essayist stated that a professor of dental pathology assured him he had never seen a dental cyst. These statements are contrary to our experiences in the infirmary of the Evans Institute. During the period of five months (October 1917 to February 1918) Dr. Wade, our radiographer, reports fifteen cysts, and we operated during that same period on twelve cyst cases. It is inconceivable to assume that cysts should be more prevalent in Philadelphia than in other parts of the United States.

INSTRUMENTARIUM.

The selection of the proper instruments necessary to carry out the operation of root resection most speedily and with an assurance of safety is largely a matter of personal equation. The instruments advocated by the writer are selected on account of their combined simplicity and usefulness. They have been tested out sufficiently to warrant their recommendation. They are—

asepsis, durability, and perfect construction has been suggested by the writer, and is giving universal satisfaction. The syringe is constructed after the well-known Luer pattern, holding 2 cc., and marked with suitable divisions on the barrel. The piston and the barrel are ground so perfectly that no washers are required to make watertight joints. An adjustable finger-rest is easily slipped over the assembled parts, and assists greatly in adjusting the needle-opening

FIG. 1.

Aseptic all-glass dental hypodermic syringe.

- (1) Dental hypodermic syringe and suitable needles.
- (2) Twisted flexible aluminum applicator.
- (3) Cheek retractor.
- (4) Flap knife combined with periosteal elevator.
- (5) Small retractor with four sharp prongs.
- (6) Dental burs.
- (7) Curets.
- (8) Gauze-packer.

Other necessary instruments, as pliers, water-syringe, powder-blower, etc., are usually included in the dental equipment, and do not need to be specially mentioned. The choice of a hypodermic syringe especially adapted to the needs of the dental surgeon is pre-eminently of the highest importance. All-glass syringes, glass-barrel syringes, and all-metal syringes are the usual types found in the depots.

An all-glass syringe (Fig. 1) that answers every reasonable demand of

in any desired direction and in exerting pressure on the piston. The piston-rod, made of solid glass, is sufficiently long to allow about two inches of space between the finger-rest and the piston-top. The space is of importance, as it allows the last drop of fluid to be expelled under comparatively heavy pressure without tiring the fingers. A removable cane-handle, made of metal, greatly facilitates the exertion of pressure on the piston. The needle-adaptor carries a universal thread so as to accommodate the hub of any ordinary hypodermic needle. The various parts of the syringe may be detached in a few moments to allow sterilization by boiling; broken parts may be replaced without obtaining a complete new syringe.

A small, strong flap knife (Fig. 2), combined with a periosteal elevator especially suitable for oral surgical work, has been recently devised by the writer. The

handle carries a short, stout, and very sharp blade, while its rear end is suitably

FIG. 2.

"Stellite" combination knife and periosteal elevator.

flattened and bent to be used as a periosteal elevator. The instrument is solidly forged out of an alloy known as "stel-

lite." The manufacturers of this metal claim that "stellite is a newly-discovered alloy of cobalt, chromium, and semi-rare metals. It resists oxidation better than any known metal except gold and platinum." This alloy is extremely hard, possessing practically no artificial temper, and the knife made from it may be readily sterilized in an open flame without the least injury. Ordinary fluids, such as weak acids, formaldehyd, and other antiseptic solutions, as well as boiling water, have apparently no influence upon this metal. The edge of the knife may be readily sharpened on an Arkansas oilstone.

Daily use of this knife in subjecting it to the routine wear and tear of an extensive infirmary practice for the last two months has proved its superiority over the ordinary steel knife. The objection which has been raised to a double-ended instrument of becoming infected in handling is readily nullified by the most important property possessed by this alloy, namely, that it may be quickly re-sterilized in an open flame.

A twisted aluminum applicator is essential for the insertion of the nasal anesthetic tampon, and a cheek retractor (Fig. 3) is useful for the purpose of distending the corners of the mouth and elevating the lips.

A small Volkmann or Murphy retractor with four sharp prongs (Fig. 4), intended to securely keep the flap in place during the operation, is indispensable. Those provided with a ring end to prevent tiring of the fingers while holding it are to be preferred. A slight bend of its shank as suggested by Williger protects the lips from undue pressure. Some operators advocate the Kilian head-band for holding the retractor, or the use of a double-ended Weitlander's self-retaining retractor, but the writer has had no experience with these accessories.

Dental burs especially suitable for this operation are round and bud burs No. 20 gage (Fig. 5), the largest pointed fissure burs, and a few small round burs. For cutting green bone the pointed plain fissure burs are recommended, while for

resecting the root-end, cross-cut tapered fissure burs, used with a saw motion, are to be preferred. To facilitate their working quality the burs should be dipped in

after its apex had been chiseled off. He is of the opinion that every dental practitioner is capable of performing this operation. The general practitioner is

FIG. 3.

Cheek retractor.

borated vaselin (1:10). Some operators advocate the use of large hand burs, and others insist upon employing a variety of chisels and the mallet or hand gouges for this operation. All of these instru-

certainly most proficient in using that utilitarian instrument, the dental engine, and there is no valid reason why he should not use it for this purpose. The keynote of this essay is simplicity of technique in a supposedly complicated oper-

FIG. 4.

FIG. 5.

Round and bud burs. No. 20 gage.

ments are expensive, require great physical force, and an undue expenditure of time. The chisel and mallet are uncalled-for in this operation; the mallet blow is always painfully felt by the patient. The writer has seen several cases where the tooth operated upon was lost shortly

ation by the elimination of all unnecessary paraphernalia.

A few simple curets for the removal of the diseased tissue from the bone cavity are most essential. Special surgical curets are not necessary. A suitable selection is made by employing scalers No. 8 or 9 and plastic instrument No. 41

(S. S. W. catalog), the latter virtually being a very large spoon excavator. (Fig. 6.) These instruments should be keenly sharpened with emery-paper disks, etc. Finally a gauze packer is to be recommended. The packer, as suggested by Luniatschek, may be readily made from a discarded gold plugger by drawing its temper, flattening out its upper end, and cutting a V-shape groove in this end so as to obtain two sharp prongs for engaging the gauze while packing the cavity. A slight curve at its sharpened end improves its usefulness.

FIG. 6.

Spoon and hook-shaped dental curets.

OPERATIVE PROCEDURES.

The patient is prepared for the operation by being covered with a rubber apron, and by protecting the head and the upper part of the body with a baby-crib sheet fastened with towel clips. Only the lower part of the face is exposed. Usually the teeth are closed together, and the floor of the mouth and its vestibule are loosely packed with cotton to absorb blood, etc.

In all cases of root resection we invariably insist that the root-canal of the involved tooth must be suitably treated and filled prior to the operation. Only in cases when operating for the removal of broken instruments do we defer the filling until after the operation, and in such a case for the reason that it may be necessary to push the obstructing agent back into the canal. As a root-filling

for this specific purpose we prefer lining the canal with a thin, zinc chlorid cement followed by a gutta-percha cone. It has frequently happened that during the process of cutting off the root-end the gutta-percha cone became entangled in the revolving bur when chloro-percha had been used.

ANESTHESIA.

The absolute *sine qua non* of a successful root amputation is the perfect local anesthetization of the parts involved. It is impossible at this moment to enter into a discussion of the various methods employed. Our clinical experience teaches us that a combination of conduction anesthesia combined with slight local infiltration undoubtedly gives the best results. The author insists that the operation must be performed with as little pain as possible. Any reasonable method or combination of methods which accomplishes the desired result is therefore suitable for this purpose. If the correct technique of injection is carried out *lege artis* the patient experiences practically no discomfort.

In operating on the upper incisors and canines the application of a good-sized nasal tampon saturated with a 20 per cent. novocain solution in distilled water and introduced by means of a twisted aluminum applicator is essential to paralyze those nerve filaments which are not reached by the injection into the infra-orbital and the incisive foramina. As a local anesthetic we use only a boiled, sterile, isotonic salt solution containing $1\frac{1}{2}$ per cent. novocain. Five cc. of this solution are mixed with three drops of epinephrin (adrenalin) solution at the time when we are ready to inject. The site of the injection is painted with a mixture of tincture of iodine 2 drams, and acetone, c. p., 4 drams, which immediately dries the tissues and leaves a sterile field for inserting the needle. The quantity of the anesthetic solution used necessarily varies with the nature of the operation. Ordinarily from 2 to 3 cc. are required for a single tooth.

The length of time necessary to intervene between the injection and the first incision varies. Usually ten minutes are allowed for ordinary nerve blocking, and at least fifteen minutes for a mandibular injection. Many operators are inclined to begin the operation too soon, and as a consequence much unnecessary discomfort is experienced by the patient. The anesthetic and the anesthetist are frequently the recipients of uncalled-for blame which, in reality, should be borne by the operator. On an average, the anesthesia lasts from forty-five minutes to an hour.

CHARACTER OF INCISION.

The most approved incision for root amputation is the semicircular cut as introduced by Partsch (Fig. 7). It allows

Fig. 7.

Patient prepared for operation. The line on the gum surface over the region of the lateral incisor indicates the direction and size of the incision.

the retraction of the formed flap without undue stretching of the adjacent parts. In both jaws, the apex of the incision points toward the teeth. The diameter of the incision should be sufficiently long—about one inch—to allow the elevation of a good-sized flap. The cut should be so gaged that its apex is about three-eighths of an inch or more if

possible from the gingival edge, otherwise necrosis of the thin band of gum tissue as a sequence of prolonged interruption of nutrition from the action of adrenalin is sure to follow.

The frenum of the lip in either jaw should never be cut, otherwise a most unsightly deformity will often result. The cut should engage the mucosa, the gum tissue, and the periosteum; an existing fistula is best engaged within the flap. With the periosteal elevator the gum tissue is lifted up and the bone is exposed. Old cicatricial tissue often causes difficulties in loosening the flap from its bony adhesions. The sharp-pointed retractor is now inserted, and if the bone is not perforated, which, however, is frequently the case on account of former abscesses, the alveolar plate is perforated with a medium-sized round bur on either side of the root to allow a large fissure bur to enter. With the latter bur a good-sized, oval-shaped window is cut so as to expose the affected root. The root-end, which is usually found to be more or less eroded, is now cut off, removed, and the edges of the root stump trimmed. The opening into the bone is enlarged with the largest bud bur (No. 20 gage) until every vestige of necrosed bone is removed, and the periapical space is scraped with the hook and spoon curets until a clean, bony cavity is obtained. Sponging with cotton or gauze tampons is frequently necessary to obtain a clear field. To facilitate close inspection, artificial light is most serviceable. In the absence of some special illuminating device a small "spot-light" can be recommended. With a large round bur (No. 20 gage) the cavity is now enlarged, and every remnant of diseased structure is removed. After sponging the cavity with a tampon dipped in warm physiologic salt solution, it should appear as clean as a "billiard ball," and the canal filling of the resected root-end must be clearly visible.

The essential point of the operation is not so much the cutting off of the root-end, as we hear it so frequently emphasized, but the painstaking curettage of

the fungoid mass from the bony cavity. The retractor is removed, the cavity is painted with the iodine-acetone mixture, and with a powder-blower a thin coating of some surgical dusting powder is blown into it. A suitable surgical powder for this purpose consists of thymol-iodid (aristol), 1 dram: boric acid, 4 drams. The flap is pressed to place and covered with a strip of sterile gauze dipped in salt solution. We never sew the flap in place.

There was a time when we religiously sewed every flap, because we were taught to do so. In time, however, we observed that in those cases where we omitted the

FIG. 8.

Mr. J. M. Photograph of case Figs. 17 and 18, one year after operation. Practically no scars are visible.

sewing the healing of the wound took place equally as fast, and with less disturbance than in those cases receiving the customary three stitches. After discontinuing sewing we tried numerous devices for covering the wound, *i.e.* plasters, pastes, wound varnishes, silver foil, etc., because of the fear of infection. In the last 100-odd cases, however, we proceeded as outlined above, merely instructing the patient to place a piece of sterile gauze, with which we provided him, over the cut surface, renewing it after each meal and before bedtime. As a mouthwash we recommend warm salt water. We caution him not to show the wound to any inquiring friends, thereby disturbing the healing edges of the wound. So far we have not seen a single case of post-operative infection. In the aver-

age case the incision closes by primary union on the third to the fifth day, and practically no visible scar remains. (Fig. 8.)

In two cases we were forced to pack the wound on account of sluggish tendencies to heal. One of these cases was a highly anemic woman receiving hypodermics of arsenic and iron at the time of operation, and in the other case (the lower incisors) slight sloughing of the soft tissues occurred on account of the incision having been made too close to the gingival line. The rationale of leaving the wound undisturbed by packing is to allow a blood-clot to form in the cavity after the vaso-constrictor effect of the adrenalin has worn off. The clot seals up the cavity effectively, and protects the edges of the wound.

POST-OPERATIVE TREATMENT.

The post-operative care consists in advising the patient to apply the hot-water

FIG. 9.

Small dental trephines.

bottle about twice a day for one-half hour over the operated side of the face. The patient should be cautioned, however, not to do this until two or three hours after the operation, *i.e.* until normal sensation of the affected parts has returned, otherwise he may severely burn himself, as we have had occasion to observe in one case. If post-operative pain is severe, 10 grains of acetyl-salicylic acid (aspirin) taken with a cup of warm tea or a glass of water usually gives prompt relief. The patient should report the next day for inspection, and again about the fifth day. A slight

touch of iodine-acetone over the region is our routine after-treatment.

As stated above, all teeth except the third molars have been operated upon

to the maxillary sinus, and consequently the accidental opening of the sinus during root resection may occur. By operating under aseptic precautions as far

FIG. 10.

by us. However, a word of caution is necessary, as occasionally the upper canines, and very frequently the second premolars and the molars lie very close

as they can be carried out in the oral cavity, no fear of infection should be entertained. Washing out of the accidentally opened sinus is contra-indicated.

In approximately thirteen of such accidents no bad after-effects were observed. It is usually followed by bloody discharges from the nose for the ensuing twenty-four hours. Owing to the above enumerated anatomic relations, at rare intervals one is forced to operate within a very limited area about the apical tissues. To avoid complications, the use of small dental trephines (see Fig. 9) in conjunction with medium sized round burs will be found most satisfactory for this purpose.

In operating upon the palatine roots of the upper molars the procedure of root resection is materially simplified by cutting off the entire root slightly above the bifurcation. By making a perpendicular slit in the gum tissue the root is exposed, cut off *in toto*, and pried out with an elevator. The cut surface of the crown end is grooved with an inverted cone bur, and veneered with soft amalgam. The next day the filling, especially the edges, are trimmed and polished. Such teeth are serviceable for many years; the writer has observed a case in which such a tooth has been serviceable for twelve years.

In the lower jaw attention should be paid to the presence of the mental foramen in the region of the apices of the premolars. The lower molars offer difficulties on account of the heavy, bony, external oblique ridge, and also in regard to their close proximity to the mandibular canal. A good X-ray picture is of much assistance in recognizing these possibilities. Removing the root *in toto* in such teeth is preferred to the excision of its apical end. The further procedures are the same as those described for the operation about the palatine roots of the upper molars.

The writer has frequently been asked, How long will it take for the new bone to completely obliterate the cavity? It is somewhat difficult to give a precise answer; as yet he has had no occasion to examine post-mortem specimens. Figs. 18 and 19 show cases operated upon a year ago, and Fig. 17 one operated upon a year and nine months ago, and it is

left to the reader to form his own conclusions.

OPERATION FOR RADICULAR CYST.

The operation for radicular cyst depends primarily upon the size of the cyst. Small cysts of about the size of a cherry are treated exactly as granulomas, while larger ones require a somewhat modified procedure. For the latter type,

FIG. 11.

Mrs. Z. Cyst extending practically over the entire hard palate. Opening made over the region of the right lateral, and counter opening over the left lateral.

the classical operation as originally suggested by Dupuytren and by Heath, but later materially simplified by Partsch, is our choice. The basic principle of the Partsch operation involves the transformation of the existing cystic cavity into an accessory cavity of the mouth by the complete extirpation of its anterior wall. The cyst is lined with secreting epithelium (see Fig. 10), which genetically is identical with that of the oral cavity, hence the absolutely sure return of the cyst when the cavity is allowed to close. As stated above, the radicular cyst is always the sequence of a pre-existing epithelial granuloma.

Radicular cysts are much more fre-

quently observed in the upper jaw than in the lower, on account of the difference of the anatomic structure of these bones. The diagnosis of a cyst in its early stages

FIG. 12.

Mr. H. J. Cyst extending over anterior part of the hard palate, operated April 30, 1917.

FIG. 13.

Mrs. Z. Appearance of permanent opening of cyst of Fig. 11, eight months after operation. Left opening closed two weeks after operation.

by physical inspection is very difficult or even quite impossible, while at a later period its size usually leads to

its ready recognition. The differential diagnosis between a cyst and a granuloma from an X-ray picture is rather simple to the trained eye. The large dark area having a sharp outline in the negative indicates its presence; in case of any doubt, a trial puncture quickly reveals its true nature. The anterior wall of the cyst is often as thin as paper, hence

FIG. 14.

Impression of present cyst cavity shown in Fig. 13, eight months after operation.

the peculiar parchment-like sound emitted on exerting slight pressure, and known as the pathognomonic sign of Dupuytren. The pressure of the fluid present in a cyst, especially a small one, is often quite pronounced. The operator is cautioned to keep this fact in mind, as otherwise he may accidentally have the cyst contents deposited in his face. Oc-

FIG. 15.

Impression of present cyst cavity shown in Fig. 12, eleven months after operation.

asionally these cysts grow very large; their formation and growth is painless, and unless they become infected the only inconvenience to the patient is the interference with speech and deglutition.

In operating upon a large cyst, the preliminary procedures are the same as those outlined above for the operation on granulomas. After lifting up the overlying soft structures the *entire* an-

terior bony wall of the cyst must be cut away. After the cyst bag is opened and its contents washed out, and the roots of the teeth projecting into it are cut

curet will readily pass through the soft tissues into the roof of the mouth, antrum, or nose, and in the lower jaw the mandibular nerve, artery, and

off, the cavity is lightly curetted, the flap folded into it, and the entire cavity tightly packed with a strip of 5 per cent. iodoform gauze. The packer de-

vein may lie exposed at the bottom of the cavity. Large cysts of the mandible predispose this bone to pathologic fractures.

FIG. 17.

Mr. J. M. A, Upper right canine. Before operation, March 21, 1917. B, Same tooth. Directly after operation, April 18, 1917. C, Same tooth. One year after operation, March 12, 1918.

scribed above is a most serviceable instrument for this purpose. Extreme care must be observed in curetting the walls of a large cyst. The resorption of bone in the upper jaw may be so complete that the

The packing is removed after twenty-four hours, when the cavity is again lightly plugged, and the gauze tampon is changed about every fourth day until the cavity is completely lined with epithelium

from the ingrowing mucous membrane. The time involved in this continuous packing of the cyst may be materially shortened by using bone-wax. Mayrhofer has introduced a most ingenious procedure for this purpose, and in the hands of those who master the correct technique the results obtained are very gratifying. In using bone-wax or "bone plombe," as this material is known, the important point to be observed is to have a dry cavity, otherwise the bone-wax will not stick. Our method may be described briefly as

may be discharged. He is instructed to wash the cavity with warm salt water by means of a soft rubber ulcer-syringe. The rationale of using bone-wax for this purpose consists in completely obliterating the bony cavity with a sterile absorbable plug. The cavity will be filled with new bone tissue from the bottom up. It may take many months before the opening is fairly well obliterated, and more or less of a depression will always remain at the site of the operation. As the operation has been performed within the oral

FIG. 18.

Mr. J. M. A, Upper left canine. Before operation, March 1917. B, Same tooth, immediately after operation, March 1917. C, Same tooth, one year after operation, March 1918. Resorption of bone about the apex has caused an opening into the antrum.

follows: The patient, sitting in the dental chair, is placed in such a position that the long axis of the cyst cavity is in a perpendicular direction. The cavity is dried with gauze sponges, painted with iodine-acetone, and then coated with a thin film of sterile paraffin oil. The bone-wax, which has been previously melted by placing the bottle containing it in very hot water, is now poured into the cavity until the latter is completely filled, and allowed to congeal. The surplus amount is wiped off. The patient reports about once a week for inspection. Usually in two or three weeks the wax has to be removed, as it is loosened on account of the moisture secreted by the ingrowing mucous membrane. As soon as the cavity is completely lined with epithelium the patient

cavity no external deformity is to be noticed.

A suitable bone-wax for the above purpose may be prepared according to this formula:

Bone-wax.

| | |
|-----------------|---------|
| R—Yellow wax, | 4 drams |
| Cottonseed oil, | 14 " |
| Aristol, | 1 dram |

Melt the wax and oil in a porcelain capsule on a water-bath; let cool, re-melt, and add the aristol. Melt over once or twice until a perfect mixture is obtained.

Regarding statistics of root amputation, it may be stated that the writer has performed this operation about 200 times without a single failure. During 1917 and up to March 1, 1918, he or his as-

sistant, Dr. J. E. Aiguier, operated on 92 cases primarily for granulomas and chronic abscesses; 17 of these cases were cysts. The average time required for an ordinary granuloma operation by employing our present method of technique is less than ten minutes, not including the injection of the anesthetic.

In presenting the technique of root amputation to the general practitioner, the writer, in harmony with the maxim of the great Boerhaave—"Simplicity is the seal of truth"—does not make any pretense of claiming originality for the method involved. He has endeavored to give credit to those who have assisted in the development of this most useful operation for the conservative treatment of those teeth which otherwise would eventually have to be sacrificed to the

forceps. Incidentally, this operation offers a rational procedure for the complete elimination of the most serious problem which confronts the practitioner of dentistry and medicine today, namely, oral focal infection. The writer merely reiterates the technique of this operation as it is practiced at present with most gratifying results in the institution with which he is connected, in the conviction that this method once more vindicates the truism of the old medical axiom of Asclepiades: *Curare cito, tute, et jucunde*.

The writer is indebted to Mr. E. G. VanValey for making the plain-line drawings, and to Messrs. A. E. and F. P. Croke and John Menzies for taking the photographs used in illustrating this article.

40TH AND SPRUCE STS.

The Nature of the Orthodontic Problem.

By A. LEROY JOHNSON, D.M.D., Springfield, Mass.

(Read before the union meeting of the Orthodontic Departments of Tufts College and Harvard Dental School, Boston, Mass., March 20, 1918.)

THE term occlusion is relatively new to science. It was coined by the dental profession to convey an idea which had long been a subject of study by zoölogists under the title of the mutual mechanical relations of the teeth of mammals. The studies of the mechanical relations of the teeth, now termed occlusion, the tooth forms, together with the anatomical structure of the jaws and skull in their relation to food habits and function, furnish the basic material upon which the science of orthodontia was founded.

From the evidence of these studies, reinforced with embryological data, a natural law, the law of occlusion, was recognized. There was seen to be, under normal conditions, a constant and ideal

relation of phenomena in the growth and development, racial and individual, of the masticatory apparatus. The order of sequence of the phenomena was seen to be so invariable that a definite conception of the normal was realized. If it were possible to follow in detail the evolution of the masticatory apparatus in an individual organism, none would be found that did not vary in some degree from the ideal. The ideal, the normal, embodied in the law of occlusion, is a conception of the normal growth and development of the dental apparatus derived from comparative studies of many organisms, fossil forms, and prehistoric skulls; it is the uniformity seen in the diversity of organic forms. The significance of this should be fully appreciated,

as it is the very essence of scientific orthodontia.

The normal relation of the occlusal inclined planes of the teeth is but a phase of the law of occlusion. Occlusion is a tangible measure of conditions, and normal cusp relation one of the factors essential to the normal function of mastication. The normal growth and development of associated structures is as vital as normal cusp relation, and absolutely essential to it. The occlusion resulting from orthodontic treatment must often be a compromise of the ideal cusp relation, as in cases of missing or malformed teeth, or as the result of the inability to stimulate physiological cell activity in one or more of the supporting structures; in other words, because of factors beyond control the absolute is no more attainable in orthodontia than in other fields of biological science. From the above it is evident that a scientific diagnosis of a condition of malocclusion cannot be made from a plaster model alone, for orthodontia is concerned with occlusion in its relation to the organism as a whole.

As clinical experience and observations have gradually defined the field of orthodontia, the meagerness of our information has become more and more obvious. Although the innate principles and natural tendencies of growth and development conform to the same general laws in the human being as in other forms of life, it has been difficult to apply the conception of the law of occlusion derived from the older general morphology to orthodontic problems. The knowledge available has not been extensive enough to explain away some of the most common difficulties experienced in practice. In fact, it has become quite evident that the difference in the essential character and life-history of the human being from the lower and prehistoric organisms demands a more comprehensive knowledge of the law of occlusion.

Until quite recently animal morphology and physiology, as ordinarily presented, have been purely descriptive sciences. The material for the study of normal histology, anatomy, and paleon-

tology has been of structures complete. Structures have been thought of as fixed in form, remaining the same throughout life. The forms of present-day organs have been attributed almost entirely to heredity, "while the vital activity of the living thing, so clearly shown in development and regeneration, has been ignored or forgotten."¹

Biological research of recent years has resulted in a transformation of the old ideas of morphology and physiology. They are being brought together on common ground. As experimental data have pointed consistently to the fundamental unity of life phenomena, the truth has become more clear that the only possible justification for dealing with the constituents of an organism as if they were separate entities is in the convenience of study thus afforded. A knowledge of morphology or physiology, taken by itself alone, conveys little information of the process of development; but in the correlation of the different points of view pertaining to these sciences, *i.e.* physico-chemical factors, physiological processes, morphological features, ecological correlations and adaptations and psychological events—in such correlation is revealed the vital phenomena of development in its real nature as a process essentially continuous.

We believe that orthodontia is in the main a study of growth and development; that it is a science of form development; that it seeks to know why structures take on the forms they do, and what is the nature of the factors which maintain the forms once they are established. We are concerned not so much with the forms as we are with the factors controlling the forms of the structures of the masticatory apparatus. We know now that knowledge limited to a description of the structure of the teeth and maxillary bones, together with the supporting and surrounding tissues, is not sufficient material on which to base the science of orthodontia—for such description shows merely the visible side of organic life, and leaves unknown the real processes of form development, form conservation, and their causes.

ORTHODONTIA A BIOLOGICAL PROBLEM.

To see nothing more in distinctive types than that each one is harmonious in design, and to be content with the assumption that the forms are due to a pre-established design and guiding force, which directs the working out of the design, will not carry orthodontia far in the field of science. The so-called "art requirements" in treatment was a valuable idea in emphasizing the harmonious character of the whole at the time when a realization of the normal was dawning in orthodontia, but it has little value now, since it conveys no conception of the nature of the factors involved in form development. It might be said that God makes the flowers grow, but who will deny that if something is known of the physico-chemical factors involved better blossoms are produced. If orthodontia is to survive as a science of human conservation it must be studied as a biological problem.

In the study of the individual organism it is logical to distinguish in the life of all parts two periods, in the first of which the part is formed prior to and independent of function, while in the second, differentiation and growth are dependent on functioning.

To W. Roux more than to any one man is due this conception of periods of developments. E. S. Russell,⁽¹⁾ in review of Roux' work, says:

The first period is one of self-differentiation, in which the parts are formed in anticipation of functioning; and the second period is one of functional development, in which the organs are perfected through functioning, and only through functioning. The first period includes the directly inherited structures, growth and development taking place before they began their specific function. The second period includes the further differentiation and maintenance in their typical form of the parts laid down in the first period, and is brought about by the specific function of the part. This period brings to pass the finer functional harmonies of the organism.

The two periods of development cannot be definitely separated from one another, nor does the transition from one to the other occur at the same time in different

parts, and furthermore, in the transition both classes of conditions are effective, *i.e.* function is building on to the already formed.

The structures with which orthodontia is most immediately concerned are the teeth, bone, muscle, vascular, and nervous.

The teeth are one of the purest types of structure of the period designated by Roux as the first. Their form is directly inherited, and it is not known to be influenced in development to any appreciable extent during the normal life activities of the organism. Their form is evolved before they are brought within the influence of the specific function for which they exist, the function of masticating, and is not improved with use, the only change being from mechanical abrasion and disease. They are, in a word, non-functional structures.

Bone is of the second period, and is one of the clearest examples of functional structures. D. W. Thompson,⁽²⁾ in his recent work entitled "Growth and Form," says:

In the biological aspect of the case, we must always remember that our bone is not only a living, but a highly plastic structure; the little trabeculae are constantly being formed and de-formed, demolished and formed anew. Here for once it is safe to say that heredity cannot and need not be invoked to account for the configuration and arrangement of the trabeculae. If a bone be broken and so repaired that its parts lie somewhat out of their former place, so that the pressure and tension lines have a new distribution, before many weeks are over the trabecular system will be found to have been entirely remodeled, so as to fall in line with the new system of forces. This process of reconstruction extends a long way off from the seat of injury, and so cannot be looked upon as a mere accident of the physiological process of healing and repair. In cases of the transplantation of bone, for example, when a diseased metacarpal is repaired by means of a portion taken from the lower end of the ulnar, with astonishing quickness the plastic capabilities of the bony tissues are so manifested that neither in outward form nor inward structure can the old portion be distinguished from the new. About fifty years ago it was discovered by Herman Meyer (and

afterward shown in greater detail by Julius Wolf and others) that the trabeculae as seen in a longitudinal section of a long bone were arranged in a very definite and orderly way.

Professor Culmann of Zurich, an engineer, recognized in the arrangement of the trabeculae the lines of stress, or the direction of tension and compression, the shearing stress being got rid of by the arrangement of the material of the trabeculae wholly along the pressure lines and tension lines. The same phenomena can be traced in any other bone which carries weight and is liable to flexure. In the os calcis and tibia it is very clear.

It is also true that the longitudinal section of a long bone of a limb which has not been used for a considerable time shows atrophy of the trabecular tissue; it almost entirely disappears.

The alveolar process of the maxillary bones, the supporting structure of the teeth, is trabecular bone, and is governed by the same condition as the trabecular portions of long bones. It is a well-known fact that the alveolar process disappears with the loss of the teeth, and is stimulated in its initial stage of growth and development by the growth of the teeth it is later to support. The pattern of the arrangement of the trabeculae is not so easily discernible as in the long bones, because of the complexity of the forces involved, but it is as truly a functional structure.

The vascular system, although literally of the transitional period, is more functional than non-functional. Only the very first rudiments are laid down in the first period of automatic, non-functional development. Russell says:

All the subsequent growth and differentiation of the bloodvessels falls into the second period, and is due wholly or in part to the direct functional adaptation to the requirements of the tissues. Thus from the rudiments formed in the first period sprout out the definite vessels in direct adaptation to the food consumption of the tissues they are to supply. The size, direction, and the intimate structure of these vessels are accurately adjusted to the part they play in the economy of the whole; and this adjustment is brought about in virtue of the peculiar properties or reaction capabilities of the different tissues of which the bloodvessels are composed.

Thus the fully formed bloodvessels are not the static structures of normal histology but are functional as bone is functional. Without the stimuli of functional activity they atrophy.

Muscle tissue is also functional. The composition of the muscle fiber out of fibrillae, and these out of muscle prisms, or again the length and thickness of the muscles, bear evidence of the functional adaptability of these structures.⁽¹⁾

Nervous structures are functional as muscle and vascular structures are functional, and their physiological character manifest in the law of habit is one of the dominating influences of activity.

The living tissues of the face and jaws are inseparably associated, particularly those of a more functional nature. They are molded together, and act and react upon one another in the constant activity of life; there can be no change in one that is not correlated with changes in the others. They are only separate entities as parts of the whole, and when one loses its composite integrity it dies. Malocclusion of the teeth, then, is probably an expression of maldevelopment of all immediately associated structures. Physiological tooth movement is tooth movement in accordance with developmental changes of all associated tissue, and not merely in the bone surrounding the root of the tooth.

It is evident that the masticatory apparatus is constituted of parts essentially different in character. The teeth are purely non-functional, inherited structures: bone, vascular, muscular, and nervous tissues are both functional and non-functional, *i.e.* as they show functional development of rudimentary structures; and the alveolar process is as purely a functional structure as the teeth are non-functional. This assemblage of structures, varying in developmental nature, is organized in anticipation of a definite function to harmonize them. The teeth are surrounded and supported by tissues whose development depends upon the stimuli of function, while the development of tooth forms, under normal conditions, is not known to be influenced in the least by function; hence, from the

physiological character of the oral tissues, the force to harmonize them is that which will adapt the functional structures to the requirement of the tooth forms, namely, the specific function of mastication.

The growth of the different parts and structures is not uniform in all directions. All manner of structural differences come into play, setting up unequal resistances. The sources of growth are not uniformly distributed; one tissue may show a tendency to increase when another does not; the bones, the intervening cartilages, and the surrounding muscle may all show different rates of increment. Under normal conditions these differences in rates of growth are harmonized by the specific function of mastication. In the absence of this specific function the definite forming influence of this part of the organism is missing, and atypical form, *i.e.* form without typical character, appears.

Phylogeny and ontogeny are not wholly distinct phenomena, but are two aspects of the one general process of organic development. In phylogeny is seen the historic values of the different structures of the masticatory apparatus in the evolution of the race.

THE LAW OF ECONOMY OF GROWTH.

The human face, nose, and jaws in an evolutionary sense are retrogressive. Social machinery, resulting from brain development, has removed to a large degree the definite forming force of the function of mastication, so dominant and vital to existence in the lower animals in securing defense and preparing food. Correlated with the development of the brain is seen a gradual recession of jaw structures. The change in the functional activity of the muscles of mastication, especially the temporals, in relation to the expanding cranium is significant. Furthermore, as the developing brain demands an even larger brain-case, the material for its expansion is drawn from the most closely associated phylogenetic and ontogenetic disused structures. The tissue upon which the expansive power of the cranium depends is the same type of

osseous formation as the bones of the face, *i.e.* dermal or secondary; they are of the same phylogenetic origin, and belong to the same meristic group of structures at the end of the cerebro-spinal system. So from the law of economy of growth, by which one structure is sacrificed for another, the dermal bones of the skull utilize in development elements essential to the stability of the bones of the face and jaws. Thus in the struggle for existence of the bones of the cranium and the bones of the face, the latter being the more non-essential, tend to atrophy.

Then, again, associated with the evolution of the brain has been a partial transformation of the function of the oral structures. With the development of spoken language the mouth has become more definitely an organ of expression. The tongue, originally an organ of alimentation, is now also an organ of speech. Dawson⁽¹⁴⁾ says, "This is perhaps the nearest approach in nature to a transformation from a physiological to a psychological function." And so as the specific function of the masticatory apparatus has been modified in its relative importance in the life activities of the human being, the structural constituents have changed correspondingly. It is a matter of common observation in morphological study that wherever the form of an organ is not essential to the existence of the individual as a whole, variation in form and structure is the natural result. There is a normal instability of organization in such parts. It is a natural condition, and it is this instability which renders these tissues so susceptible to and expressive of fluctuations in the physiological balance of the organism as a whole.

Metchnikoff⁽¹⁵⁾ unreservedly considers the teeth as disharmonies. He says they are out of harmony with the fundamental needs of the race, but adds later on, "It cannot yet be said that they are useless and harmful." A well-known anthropologist says that one of the greatest problems of the medical science of the future is the disposition of the teeth. He sees them as structures fast becoming disharmonic and injurious possibilities.

Although I have only touched in a very fragmentary way the great place of orthodontic structures in evolution, I hope it is clear that scientific orthodontia cannot ignore the facts of phylogeny.

But the problem of orthodontia cannot be disposed of in so general a way for it is concerned with individual elements in each case. The general method of procedure followed in treatment seldom considers anything more than tooth forms. There is little, if any, effort made to determine, to say nothing of influencing, the etiologic factors of which the malocclusion is expressive. In the majority of cases and in much the same manner appliances are adjusted, and the teeth are pulled and twisted into an occlusion like so many stones, while the phenomena upon which the final retention depends are, with the one exception of cusp relation, absolutely ignored. And we know from the racial and individual history of the human being that cusp relation of the teeth is becoming less and less a controlling factor of development. If it were the dominant force which ordinary methods of treatment attribute it to be, malocclusion would not be so common.

The fact is that ordinary methods of treatment recognize in the mutual mechanical relations of the teeth the only difference between individual cases, and proceed upon the belief that the oral structures of all individuals possess the same possibilities of development.

Our public educational institutions are founded upon the same plan in that the same system of instruction is applied to all children. The individual characteristics and innate tendencies of the individual mind are disregarded. All minds are molded to the same system instead of the system being adapted to the distinctive needs of the individual. Since the majority believe that the object of our public schools is to elevate the average intelligence of the masses, perhaps the present method is the best. But in orthodontia, where the object is the betterment of the individual and the problem one of development, it is as imperative to consider the nature of the organ-

ism as it is to consider the environment in which it lives. Thus we come face to face with the central problems of biology—heredity, the interdependence of function and structure, and the fundamental unity of the organism as a whole.

INFLUENCE OF FUNCTION UPON FORM DEVELOPMENT.

The term function as generally used is limited to the expression of the specific activity of the individual organ or part, as the digestive function of the stomach or the secretory function of a gland, but in the study of form development it takes on a more comprehensive meaning. It expresses all of the dynamic processes of the living organism; the complex of chemical reactions: the action, reaction, and interaction of organs and parts in the adjustment of life. Interpreted in these terms, the fundamental unity of function and structure are beyond question.

To maintain as some do that structure is the cause of function, and that the structural organization of the organism arises independently of function, making function possible; or, on the other hand, to hold that function is the cause of structure and that the problem of development is the change which takes place in the functions and habits, is, in either case, a failure to recognize but one phase of organic life. Neither function nor structure is the *cause* of the other: they evolve together, and each modifies and conditions the other. "They are merely different aspects of organization, and are dealt with separately by morphologists and physiologists as a matter of convenience."⁽⁶⁾ Child⁽⁸⁾ says that the dynamic processes do not constitute life in the absence of the colloid substratum, nor is the colloid substratum alive without the dynamic processes. In fact, neither function nor structure is conceivable except in relation to the other; they are interdependent and inseparable, and anything which modifies one, of necessity modifies the other also. To deny either is to dispute an essential element of life.

Although in all probability deformities

are for the most part due to environmental causes, it is quite clear that the factors of development are in the germ, the inherited element, as well as in the environment, in both the intrinsic and extrinsic forces. The directing factors of development are in the main intrinsic, and are in the organization of the germ cells, while the environmental factors, the extrinsic forces, exercise chiefly a stimulating, inhibiting, and modifying influence. We cannot regard specific forms of structure as caused by external influences: "The egg of a fish and that of a polyp develop side by side in the same body of water, under identical conditions, each in its predestined form."⁽¹⁵⁾ Conklin⁽⁶⁾ says, "The entire organism develops out of the germ and the organism of the germ determines all of the possibilities of development, though the actual realization of any possibility is dependent upon environmental stimuli." Heredity fixes the possibilities of development; it sets bounds which cannot be passed.

The form which structures take on is the result of the interaction between a complex of dynamic changes and the colloid substratum: it is the result of the interaction between function and structure: it is never entirely determined by function or by structure; it is conditioned by each. Nevertheless, it is safe to say that function is the constructive agency in form development, and that the inherited element in the organization determines the possibilities of development. H. F. Osborn,⁽³⁾ in his recent work, "The Origin and Evolution of Life," says of the creative power of function—"So far as the creative power of energy is concerned, we are on sure ground: in physics energy controls matter and form: in physiology function controls the organ: in animal mechanics motion controls and in a sense creates the form of muscles and bone. In every instance some kind of energy of work precedes some kind of form, rendering it probable that energy also precedes and controls the evolution of life." Thus whatever form the structural elements of the masticatory apparatus may assume,

typical or atypical, it is an expression of the interaction of function and structure; and, furthermore, of especial significance to orthodontia is the influence of the organism as a whole upon the life activities of any of its parts.

The living organism as a whole is a unit. It possesses certain properties characteristic of the organic whole rather than of the sum of the vast number of smaller units of which it is composed. To draw a rough parallel: Just as the properties of water are peculiar to the molecule and cannot be accounted for as the sum total of the properties of the atoms of hydrogen and oxygen, so the properties of the organism are connected with its whole organization, and not simply those of its individual cells or units.

The experimental research of Loeb,⁽⁴⁾ Morgan,⁽⁵⁾ Child,⁽⁸⁾ and others upon growth, development, and particularly regeneration, show that these fundamental phenomena of life involve the organism as a whole. They also show the dominance of the whole over any of its parts, and that interconnection of parts is one of the chief peculiarities of an organism. It is not known at present just what the organizing principle is that controls and molds the growing and developing organs and parts into a harmonious whole, but it is well established that there is an internal perfecting agency. Investigations relative to the effect of the internal secretions of the ductless glands is determining the fact that the organizing force may be found in the circulation of the internal secretions of all tissues. Mathews⁽¹²⁾ says:

The body is an organic whole, and these so-called organs of internal secretion are not unique, but the bones, muscles, skin, brain, and every part of the body are furnishing internal secretions necessary to the development and proper functioning of all the other organs of the body. Such a scheme to be complete must embrace every organ; only the barest beginning has been made in this study, so important, so necessary for the understanding of development and inheritance. The problems of development and inheritance cannot be solved until these physiological questions are answered.

Other investigators seem to be of much the same opinion. Loeb,⁽⁴⁾ in his "The Organism as a Whole" says, in reference to Mendelian heredity:

It is not yet proved that the organism is nothing but a mosaic of Mendelian characters, but no writer can be blamed for considering such a possibility. If we assume that the organism is nothing but a mosaic of Mendelian characteristics, it is difficult indeed to understand how they can force themselves into an harmonious whole—even if we make ample allowance for the law of chance and the corresponding wastefulness in the world of the living. But it is doubtful whether this idea of the rôle of Mendelian factors is correct. The facts of experimental embryology strongly indicate the possibility that the cytoplasm of the egg is the future embryo, and that the Mendelian characters only impress the individual characters upon this rough block.

He then gives the evidence, and adds:

If the egg is already the embryo in the rough, we can imagine the Mendelian factors as giving rise to specific substances which go into the circulation, and start or accelerate different chemical reactions in different parts of the embryo, and thereby call forth the finer details characteristic of the individual.

Castle, in his work on "Genetics and Eugenics,"⁽¹⁾ in discussing Acquired Character says: "That a mechanism for the transmission of acquired characters from the soma to germ-cells has as yet not been demonstrated, does not of course disprove the existence of such a mechanism. Such phenomena as memory, having its basis in the nervous system, and as the control of development and of behavior through internal secretions, give us grounds for believing that an adequate basis will be found when our knowledge of the organism becomes more complete."

Whatever the future may bring forth relative to the nature of the elements involved in the interaction of organs and parts, experimental medicine and biology seem even now to have gone far enough to proclaim the universality of the interaction principle. The recent investigations of Crile,⁽¹¹⁾ Cushing, and Cannon also show clearly the necessity of a

complete biologic picture of the organism as a whole when studying any of its parts.

Therefore, in the light of its historic nature, racial and individual, the orthodontist must see in the development of the oral structures a manifestation of the life activities of the organism as a whole. The evidence of science is explicit that the masticatory apparatus is a dependent and living part of a living organism; that it is controlled in its growth and development by the same factors which control the growth and development of the organism as a whole, and that it is expressive of both physical and psychical phenomena.

And since the form of structure is the result of an interaction of forces determined by heredity and environment, the question of etiology is a consideration of the factors which affect the organization of the individual or modify the stimuli of the environment sufficiently to disturb the equilibrium expressed in normal development. Consequently the great problem of orthodontia is to distinguish between these two classes of factors, between nature and nurture, and to control development, so far as it may be possible, through the knowledge thus gained.

It will be difficult, doubtless often impossible, to determine the relative value of environmental and hereditary factors in malocclusion, but until we realize something of the true nature of the forces we profess to control, until we realize that we work not upon dead forms, but upon living things, orthodontia cannot withstand the crucial test of practical utility. Because in treatment we employ mechanical means is no reason why we should forget that we do so to stimulate biological processes.

Restorations with Jacket Crowns.

By J. F. HOVESTAD, D.M.D., Boston, Mass.,

LECTURER AT HARVARD DENTAL SCHOOL IN CROWN AND BRIDGE WORK; AUTHOR OF "PRINCIPLES AND TECHNIQUE OF CROWNS AND BRIDGES."

INTRODUCTION.

A NOTED writer quotes the following: "It must be forever true, that before the beautiful in art or nature can be expressed, or even appreciated, a sense of the beautiful must be gained and carried in consciousness."

Since Dr. Land first described the jacket crown thirty years have passed, and it is surprising to see how few men have realized the beauty and practical value of this truly "ideal crown." The profession owes Dr. Land a great debt, and I take this opportunity to express my deepest appreciation for this great gift to our profession. I am realizing more and more Dr. Land's desire for beauty and perfection, which is so evident in this beautiful crown. And when I say "beautiful crown," I do not refer only to its esthetic appearance, but also to its manifold advantages and features, which are enabling me and my fellow practitioners to solve some of the great problems that confront our profession in the saving of teeth and pulps.

This crown eliminates to the greatest extent the devitalization of pulps, and in its appearance approaches nearer to nature than any other restoration in the past, or at the present time. Very often it deceives the eye of the skilful dentist. The jacket crown is not only useful for single teeth, but can be successfully used in the following ways: To correct irregularities. To raise the bite. To change the bite. There are various types of jacket crowns, but the type I am using extensively is known as the "all-porcelain jacket crown."

VARIOUS TYPES OF JACKET CROWNS.

(1) A porcelain veneer fused to the labial surface of a platinum *plate* shell, cementing the shell with porcelain to the prepared tooth.

(2) Porcelain built up and fused to a perforated platinum *plate* shell, previously fitted to the prepared tooth, cementing the shell with porcelain to the prepared tooth. (Dr. W. G. Bridge.)

(3) Dr. Land's "overlap." This

crown overlaps the tooth mesially and distally, leaving the lingual portion of the tooth uncovered. The porcelain is baked over a platinum *foil* matrix, and this matrix is removed before cementing the "overlap" crown to place.

(4) The building up and fusing of porcelain over a platinum *foil* matrix, or cap. This platinum matrix can be made by the direct or the indirect method and is removed from the finished porcelain crown before cementing the crown into place. This crown is known as the all-porcelain jacket crown.

THE ALL-PORCELAIN JACKET CROWN.

I shall endeavor to describe and illustrate in this article the construction of this crown, dividing the operation into two parts—*operative* and *ceramic*.

In describing the operative part the operator will be shown the necessary steps for the preparation of the tooth, the impression-taking, and the bite; in the ceramic, the making of the crown will be described, including the making of the die and matrix.

Part I: Operative.

PREPARATION OF THE TOOTH.

When deciding upon a jacket crown, it is absolutely necessary first of all to determine the condition of the pulp and general conditions of the tooth or roots related to its foundation and occlusion, upon which we are to build. (Radiographs of the teeth are most valuable aids.)

First: If one is dealing with a vital tooth, every precaution and care must be taken to produce a good tooth preparation without the least injury to the nerve system of the tooth.

Second: When dealing with a "devitalized tooth," all precautions necessary should be taken to sterilize and fill the roots of the tooth, and in many cases it is necessary to build up portions of the lost tooth or root with a suitable material in order to strengthen and preserve the root and to produce a well-prepared seat for the jacket crown.

The use of local anesthesia (novocain) is of inestimable value to the patient as well as to the operator, in order that the necessary "ideal tooth preparation" may be obtained. The technique of the various injections of novocain has been minutely described in my book, "Principles and Technique of Crowns and Bridges."

VITAL TOOTH PREPARATION.

After the tooth with a vital pulp has been anesthetized, a vertical cut on the mesial and the distal sides of the tooth is made with a thin wet carborundum or rubber and carborundum stone. The cutting should be done from the cutting edge toward the neck of the tooth, producing a shoulder at the neck, as shown

FIG. 1.

in Fig. 1. The cutting is done in this manner on both the mesial and distal surfaces of the tooth.

A little thicker stone, but smaller in diameter, is then used to reduce the palatal and the labial surfaces of the tooth, so as to remove the contour and bulk and produce a shoulder at the neck palatally and labially, as shown in Fig. 2.

The cutting edge or occlusal portion of the tooth is ground down to allow for a suitable thickness of the crown. The tooth now presents a rectangle with four well-defined corners. These four corners can be reduced with a wet concaved carborundum stone (Fig. 3), or with a square-end cross-cut or plain square-end fissure bur. (Fig. 4.)

When cutting a tooth with stones for a jacket crown preparation, a steady stream of water should be flowed over tooth and stone from a water syringe.

This is of great value, for the cold (or warm) water dissipates the heat generated, permits more rapid and efficient cutting, and surprisingly reduces the

used, with an upward pressure (that is toward the root), to deepen the shoulder. (Miller.) (Fig. 4.) This is followed with a fine stone to produce a perfectly

FIG. 2.

FIG. 4.

pain from grinding vital teeth. (These syringes are called "hydro-tractors.")

The cutting with the fissure burs should be done from the shoulder at the palatal side toward the mesial, from the

smooth surface of the cone-shaped tooth and shoulder.

The prepared tooth is now carefully washed, dried, and painted with a rosin solution or a suitable cavity-lining pre-

FIG. 3.

FIG. 5.

mesial toward the labial, from the labial toward the distal, and from the distal toward the palatal surface. This is necessary to avoid vibration and facilitate steady cutting. It is very important to cut with these square-end fissure burs in a semicircular direction.

A plain square-end fissure bur is now

paration. This very important step is in order to protect and close up the tubules of the tooth. It also prevents after-pain and affords great protection against infection and thermal changes.

IMPORTANCE OF THE SHOULDER.

The all-porcelain jacket crown "tooth preparation" must be ideal, that is to

say, the shoulder must be cut completely around the tooth under the free margin of the gum. (Fig. 5.) It is not necessary to cut the shoulder deep into healthy tooth structure, but in decayed places at the cervical margin it should be extended down to the depth of the decay. The tooth walls should be trimmed straight and regularly without grooves or cross cuts, undercuts, or overhanging edges on any surface.

The great strength of this crown lies in its close adaptation to the perfectly prepared tooth, thus meeting the stress put upon it with the full length of the crown.

PULPLESS TOOTH PREPARATION.

A pulpless tooth, that has been properly treated and the roots filled may be prepared in the same manner as the vital tooth. If, however, the pulpless tooth is badly broken down, or has had a post crown previously, the root must be first built up properly with cement, or in most cases with a metal inlay. In order to build up such roots, gold or other metal castings should be made, so as to fit the canal and pulp chamber or decayed cavity perfectly, and also provide for an extension above the root, similar to the tooth stump left above the gum margin of an "ideal tooth preparation." (Fig. 5.) Gold or the S. S. W. Co. Weston's metal are very practical for this purpose. After the casting has been cemented to place, the shoulder may then be cut at the neck of the root. The porcelain jacket crown encircling the root will act as a Richmond band and prevent splitting of the root. (Figs. 6 and 7.)

After the shoulder is cut, the prepared root with its inlay or casting presents the same shape as that of a vital tooth preparation, and the succeeding steps are the same for both. The shoulder affords a perfect seat, and with it perfect margins and perfect carving and contouring may be obtained. It is usually at this point (at the gum margin) that all other crowns fail. By leaving no overhanging band we avoid gingival irritation, and with a good seat at the shoulder

under the free margin of the gum, out of the danger zone of recurrent caries, we come nearest to natural tooth condi-

FIG. 6.

tions in the making of the all-porcelain jacket crown.

There is no material that is so favorably received by the gum tissue as is

FIG. 7.

porcelain. The gum actually hugs the porcelain, thereby preventing the entrance of foreign matter at this point, whereas, with other crowns, pockets are often formed which become the seat of septic foci.

TAKING THE IMPRESSION.

In taking the impression the tooth should be first coated with vaselin. A

FIG. 8.

FIG. 9.

seamless copper band is fitted loosely around the prepared tooth, but closely to

the gum margin. (Fig. 8.) The copper band is now filled with Kerr's modeling compound, and the impression taken. This impression should show the sharp outlines of the prepared shoulder at the neck. (Fig. 9.)

If the first impression does not prove satisfactory, dry it, add a thin layer of very soft compound over the surface, and press quickly over the tooth. This will produce a compact and sharp impression.

The band is now marked in order to distinguish the labial and buccal sides.

COLOR OF TEETH.

Selection of the proper color of the tooth is made in the usual manner. It is best to select the shade with a porcelain shade guide containing the colors of the particular porcelain from which the jacket crown is to be made. S. S. W. 2510, Justi's, Morfat's, or Consolidated porcelains are recommendable.

TAKING THE BITE.

In taking the bite a roll of soft S. S. W. paraffin pink wax is worked over the prepared tooth and adjoining teeth, and the patient requested to bite into the wax (a so-called "squash" bite), which is then removed and chilled. Dry off all moisture from the wax, and with a wax stick melt more wax into this wax bite of the prepared tooth, quickly press it back over the teeth, and again allow the patient to bite, after which it is again removed and chilled. The wax bite will show sharp outlines of the prepared tooth and the adjoining teeth as well, and can be used for both impression and bite.

The taking of this impression and bite for the jacket crown is far more difficult than it may seem to the average operator, and requires great care and accuracy. I have used many other methods for taking the bite, but the one described is the simplest and most practical, if followed carefully.

PROTECTION OF THE PREPARED TOOTH.

It is necessary to protect the tooth against thermal changes during the construction of the jacket crown. The following is a very simple method of accomplishing this: A strip of white base-plate gutta-percha as wide as the desired

FIG. 10.

length of the crown is warmed and rolled once or twice around a smooth excavator handle, according to the width of the space.

The gutta-percha tube being trimmed to the outline of the gum margin, is softened over the alcohol flame, pressed

FIG. 11.

and shaped into proper position over the prepared tooth. With a little practice one can very quickly make a good gutta-percha covering, and it is most surprising how tight this covering will be and how well it will keep its shape and protect the tooth from ordinary wear. It is also of great value in keeping the gums from closing over the prepared shoulder. (Figs. 10 and 11.)

Another method of protecting the prepared tooth is as follows: Fit a Caulk's celluloid tooth form over the prepared tooth, being sure that it is large enough at the neck to fit *over the outer edge of the shoulder*.

The prepared tooth is coated with vaselin, the tooth form filled with a suitable cement and pressed into place over the tooth. (Fig. 12.) Watch the setting of the cement closely and remove the tooth form with the cement just before the cement sets. When the cement is perfectly hard, trim off the surplus, dry both the prepared tooth and the covering, and set with chloro-percha or temporary stopping.

Fig. 12.

I have often filled these tooth forms with S. S. White temporary stopping, and while soft pressed it over the prepared tooth, obtaining very satisfactory results. The Caulk's tooth forms will keep their shape, withstand mastication, and on account of their smoothness make splendid temporary coverings.

Another successful use of the celluloid tooth form is as follows: The celluloid form is first trimmed for length and contour, and then filled in with silicate cement (using two or more colors if necessary) to match the adjoining teeth. This cement tooth form can remain on the tooth until the jacket crown is ready to be set.

Care must be taken to first varnish the prepared tooth and coat it with vaselin before cementing the celluloid tooth form into place. The vaselin prevents

the cement from sticking to the sensitive tooth.

To remove the cement tooth form use a thin rubber carborundum stone and cut through the cutting edge of the cement tooth form almost to the prepared tooth. Then take an enamel chisel and pry apart the cement, which will usually break away from the tooth in three pieces.

FITTING OF THE PORCELAIN JACKET CROWN.

Remove the temporary tooth form, or covering, and clean the prepared tooth of all particles of gutta-percha or cement. Great care must be exercised in trying the crown on the prepared tooth to do it gently, so as to avoid any pressure on the crown, before it is cemented into place and the cement has hardened.

Grind the mesial or distal sides of the jacket crown, if necessary, until the crown is seated, being careful not to grind off too much, as there is a possibility of losing the contact points with the adjoining teeth.

There is no other crown made that will seat itself at one and all times so perfectly as the all-porcelain jacket crown.

CEMENTING THE CROWN.

In cementing the crown to place we first carefully dry the prepared tooth, using chloroform in the case of vital teeth, as it is less painful than alcohol, but care should be taken not to remove the tooth lining with which the tooth was painted after grinding. If the lining is removed, it is most advisable to give the tooth another thin coat.

For almost all jacket crowns a light-yellow cement is most satisfactory, and is not liable to change the color of the crown. The cement should not be mixed too thick, and when the jacket crown is filled to the rim the crown should be carried over the prepared tooth with a

light rotary pressure until seated, and then held in position until the cement

quire absolute accuracy and care to the smallest detail.

FIG. 13.

FIG. 14.

has hardened. To prevent air becoming confined in the bottom of the crown,

FIG. 15.

use a jiffy tube for filling in the crown with cement.

Part II: Ceramic.

The construction of the all-porcelain jacket crown, the making of the metal die, and the articulation of models, re-

MAKING THE METAL DIE.

A strip of thin plate wax, tin foil, or paper is forced around the tube impression and is extended about $\frac{1}{2}$ inch over the tube. This is then embedded in plaster. When the plaster has hardened the amalgam is packed into this impression and built up to a pyramid shape. (Fig. 13.)

In packing the die, care must be taken to squeeze out all surplus mercury. Begin packing with soft pieces, then follow with dryer pieces, and when brought to the level exert pressure and squeeze out as much mercury as possible. In my own practice, I use special die amalgam for all crowns and inlay dies, but copper amalgam may be used with good results. All impressions packed with amalgam are left over night to harden sufficiently.

After removing the plaster core, the extending metal is marked on the side corresponding to the mark on the tube of the impression. These marks indicate the front of the tooth and prevent the misplacing of the die on the model or wax bite. The tube impression is separated from the die with warm water.

With a sandpaper wheel on the dental lathe the root-end of the metal die is now reduced to the desired shape. The die is then placed into the wax bite very carefully and an articulated model is made. (Fig. 14.) A hole is carved through the lower end of the model, to reach the base of the metal die, and the metal die pushed through the hole from the plaster model. (Fig. 15.)

MAKING THE MATRIX.

In making the matrix 1/1000 platinum foil is used. For anterior teeth it is cut and shaped as shown in Fig. 16, A; for bicuspsids and molars a strip is cut and folded in at the top by cutting on two sides. The excess of foil is trimmed to allow the fold to be double-lapped,

making a matrix with a double-folded lap to the mesial or distal side of the tooth (Fig. 16, c), using long-nosed cotton-pliers to fold the foil. This joint does not need to be soldered.

We next twist, or turn over, the upper

be easily removed from the die, melt sticky-wax over the matrix to edge of shoulder; this will permit its easy removal, after which the wax may be burned off by holding the matrix in the open flame.

FIG. 16.

end of the foil (Fig. 16, b) and cut off the excess, but allow for the closing of the top. The foil is formed with finger pressure to the die, the edges burnished with gold burnishers, put into the swager, and swaged carefully. It is necessary to burnish the foil well into

The porcelain is built on with a fine brush little by little, drying and baking, repeating this operation until the case is finished. (Fig. 17.)

If the operator desires, practically the same result may be obtained as follows: A piece of base-plate wax is wrapped

FIG. 17.

FIG. 18.

the shoulder groove, getting a perfect adaptation to the groove and the edge and sides of the die. (Fig. 16, E.)

We now remove the matrix from the die, trim the overhanging edges, replace the matrix on the die, reburnish, and swage.

If for any reason the matrix cannot

once around the lower end of the die, extending over the platinum foil *to the edge of the shoulder*. (Fig. 18.) Again wrap a piece of paper twice around the die, extending from the lower end to the desired height of the crown *above the shoulder*, gluing or tying the paper firmly.

PACKING IN THE PORCELAIN.

In packing the porcelain we first mix the two colors of porcelain that are to be used, keeping the colors separate, and begin packing with the body or neck color, in a similar manner to that in which we pack amalgam into an impression of a metal die. The thickness of the base-plate wax will allow plenty of space for the porcelain between the paper wrapper and the platinum matrix.

Enough of the yellow or base porcelain is packed in to cover the shoulder and the entire matrix. This base color porcelain should be trimmed off in a slanting direction from the periphery of the neck to the upper end of the matrix, before the second or enamel color porcelain is added, which will permit a fine blending of the two colors.

The filling-in of the porcelain has to be done slowly, in order to permit perfect drying. The drying and packing of the porcelain is done as follows: A suitable serrated instrument handle is rubbed back and forth on the lower rough end of the metal die, causing sufficient vibration so that the porcelain will settle close to the matrix and bring the moisture to the surface. The moisture is then dried off with a piece of cloth, or blotting paper. This operation is repeated from twenty-five to seventy-five times, until the desired height of the crown is obtained. The vibrating and drying of the porcelain is most important for the successful handling and finishing of the crown.

SHAPING AND CARVING THE PORCELAIN.

The paper and wax bands are carefully removed from the die and porcelain, which is now very much like chalk as the result of the vibrating and drying, and can be easily handled and carved. The excessive fulness in the circumference of the crown is just about sufficient to allow for the shrinkage in baking the porcelain.

The rough carving and shaping is

done with thin knives and carving instruments. It is necessary to trim away some of the adjacent plaster teeth on the plaster model, in order that the die and porcelain may be placed on the model for the final carving. The matrix with the carved porcelain is then re-

FIG. 19.

moved from the model and metal die, and the porcelain baked to a dull glaze. When cool, the crown is again placed on the metal die and plaster model, and porcelain is added to give the desired shape, contact, and articulation. In the

FIG. 20.

X-ray of case shown in Fig. 19.

final baking the porcelain should be carried to a "glass" fuse.

To remove the matrix the platinum foil should be carefully pulled away from the edges toward the middle of the crown.

The making and baking of twin crowns (see Figs. 19 and 20) is simply

220 MARLBORO ST.

Restoration of Abnormal Mouths by Surgical Treatment before Inserting Plates.

By JAMES P. RUYL, D.D.S., New York, N. Y.

(Read before the Northeastern Dental Association, at its annual meeting, Worcester, Mass., September 26 to 28, 1917.)

AMONG the many things which come to our notice in connection with daily practice are certain abnormalities which occur in the anterior teeth in their relation to the upper and lower jaws. Our interest, as well as a desire for making corrections, has always been excited by them, but they have baffled our efforts for many years. How often do we find mouths with partial dentures replacing the lost bicuspid and molars where the anterior upper or lower teeth—in most cases the uppers—stand out of position, with consequent protruding lips, because of faulty occlusion, and how many times have we seen dentures worn which constantly moved while the wearer was talking! Again, patients come to us who, for want of artificial dentures, show their gums during ordinary lip-movement, and when we are called upon to make plates for them we wish they had never come to our office, or we send them to the other man, so that when relatives or friends inquire as to who made their plates, the blame may not rest on us. We have all noticed these unsightly mouths as we go through the streets or sit in front of them in street cars, and while we realized that something might be done to make these people presentable or even good-looking, we inwardly hoped that nothing similar would come to us for correction.

Perhaps just as well here as anywhere a far-reaching ethical point may be mentioned. I refer to the embarrassment and sensitiveness which abnormalities of

any kind bring about. Doubtless all of us have noticed how people with bodily defects have held back, painfully conscious, from mingling with others; how the happiness and freedom of spirit and even the progress of the individual has been impaired. I have known patients to cover an unsightly mouth with their hand and even refrain from smiling, and I myself have rejected an otherwise competent applicant for work because of some dental defect.

Now, for convenience I shall divide the conditions which arise from these abnormalities into four general groups. It is my intention to state them with their causes, and to give an effectual method of correction.

The first and most common one we meet, and one of the most difficult to rectify unless properly handled, is that condition which is brought about because the patient has only six or eight anterior natural teeth, bicuspid and molars having been lost, and has worn an upper denture for many years. In his endeavor to reach for food while chewing these natural teeth have gradually become loosened and elongated, and there has been a marked forward movement of the process and the teeth, with a consequent thickening of the lower lip, and the appearance of a protruding jaw, often resulting in extreme cases of pyorrhea.

In the mouths of such patients great absorption takes place in the anterior portion of the upper jaw, caused by constant hammering of the lower teeth upon

the upper, the upper receding to such an extent that they cannot be seen, giving one the impression that there are no teeth in the upper jaw at all. If one wished to make an upper denture for a patient having such conditions in the lower jaw as stated, it would be impossible to construct one that would be satisfactory, because of the lower teeth having become elongated to such an extent that they extend above the line of the occlusal plane—often as much as an eighth of an inch. If we set the centrals and laterals of the upper denture their proper length—about one-sixteenth of an inch below the upper lip line—we should create a condition in which the patient could not close his lips. Now, if we allowed the lips to meet, and did not make a correction in the lower jaw by removing the lower teeth and process, we should have to set the upper teeth so high that there would be an appearance of no teeth in the upper jaw. The result would be a sagging of the mouth, changing what may have been an animated and pliant face into one with a set stern and aged expression, and the new plate would be no better than the old one. My point is that without removal of the teeth and an operation we could not relieve the abnormality.

Next there is the abnormality due to a natural condition where the gums are long and the lips are short. People with such mouths are generally discouraged with their appearance, conscious of their defect, and, being hopeless of any improvement, are prone to neglect their teeth even to the necessary fillings. They lose their teeth early, and the dentist, in making a denture, fits the teeth to the gums, usually with no rubber against the ridge. The teeth must be ground right up to the gum, and in a short time there is an unsightly space between the gums and the teeth. Such a denture is usually very difficult to keep in position and get any degree of comfort in mastication.

The third abnormal condition, due to adenoids, thumb-sucking, and irregularities, is a pointed arch with the teeth slanting forward. Now, when such pa-

tients come to us there is no longer any possibility of regulation, usually because there are too many teeth lost, or the patient is too old and does not care to undergo treatment for correction of the irregularity.

The fourth abnormal condition is one in which dentures have been worn for many years, and in which the process has been entirely resorbed, leaving a soft flabby ridge. When it falls to the lot of the dentist to make a denture for a mouth of this kind, he, to make a good fit, puts an extremely deep air-chamber in the plate, which causes the mucous membrane to pull down and form a cauliflower-like appearance of the tissue, and because of constantly increased flabbiness, not only of the ridge, now, but also of the palatal portion, there is more movement of the plate than before.

All these four conditions must be treated surgically. To leave an unsightly condition, or to augment it, as most dentures will in an abnormal mouth, is not doing justice to a patient. As much of the superfluous process must be removed as will in the judgment of the operator restore a natural comeliness, and in many cases an improvement over nature. Even after the removal of a tooth, in cases where one does not expect to make a facial restoration, it would be advantageous both to the dentist and the patient if, at the time of extraction, the sharp pieces of process that remain where the cervical border of the tooth was were removed. This is often the case with the canine, where the process is a little thicker and more prominent. By so doing we not only hasten the time when we can take the impression, but also save the patient many hours of pain. The sharp prominences that are left by not removing the process are troublesome in eating, etc., and the thin membrane that stretches over it is only a slight protection to the process underneath, and makes it consequently very susceptible to pain.

Those cases with very soft ridges and no process underneath, the process being entirely resorbed, must be treated surgically also, by removing the tissues until

there is just a thin portion of the membrane over the bone. By so doing we place the mouth in a condition where the plate rests on a solid foundation, thus preventing its shifting, which would not be the case if the soft tissues were left. It is the same in principle as trying to build a house on a foundation of sand. The operation both for hard and soft tissue is so simple, so easily done—only an obstruction to remove—that it would be more natural to do it than not.

TECHNIQUE OF THE SURGICAL PROCEDURE.

With the exception of that condition where soft membrane is present, all abnormalities caused by bony prominences are treated in the same way. Novocain or a general anesthetic may be used; I prefer the former. If it is necessary to operate in both jaws make the injections in the upper and lower at once, and after loosening the gum around the teeth with a lancet, extract the teeth only in one jaw and remove the process. When that is finished remove the teeth from the other jaw, first loosening the gum around them as before, and remove the process. My reason for working in this way is to avoid the sponging of blood in places where you are not operating. After removing the teeth, place a blunt instrument, about a quarter of an inch wide, shaped somewhat like an ordinary wax spatula, between the process and the gum, and by leverage, using the process as a fulcrum, tear the muco-periosteum away, leaving the bone perfectly clean. This is easily done, far more easily than dissecting the gum, and causing much less bleeding. Now hold the gum-flap back, and using a bone forceps or, better still, a curved wedge-cutter, cut off as much process as necessary. The sharp edges which are left palatally and labially must be rounded off with a bur or engine stone; apply water with a syringe while doing so.

We now have the flaps of gum hanging down anteriorly and posteriorly, and they can be very easily cut off with gum scissors. Remove enough gum

tissue so that the parts will not quite meet when pressed together over the process with the finger and thumb, leaving a space of about one-sixteenth to one-eighth of an inch. By thus not allowing the membrane to come together absolutely, it will be found that when the healing takes place the gum will reach over the bone and leave a firm healthy ridge. It is not necessary to use sutures at any time. Absolute healing takes place and in from a month to six weeks permanent dentures can be made. I have taken impressions for temporary plates in from five to ten days after such operations, and they were worn for from one to two years. In the operation for cases where there is a pointed arch it is generally necessary only to remove the outer plate of process in order to get the lip back to normal. One need not cut off the whole process—only the anterior portion—because in these cases the gums do not show so much, and we only want lip restoration.

For the operation upon soft flabby ridges the anesthetic injection is made in the same manner as before. Instead of beginning at one side of the ridge and cutting entirely across to the other side, begin in the center of the soft tissue and cut on one side almost to the end, leaving only enough attachment to keep the flap from dropping; then begin from the center again, and cut entirely across to the other side. The flap will now be suspended by a small piece, which can easily be clipped off. By doing this we prevent the flaps from getting in the way while operating. In these cases healing takes place so rapidly that impressions can be taken within a week or ten days. The cauliflower-like soft tissues, caused by extremely deep air-chambers, are removed in the same manner, except that a curved lancet is used. The tissues should be shaved down to the periosteum.

Such radical changes as this operation makes in the facial expression very often bring us into difficulties with the patient's family, because they have been so accustomed to the old expression that, when a correction is made, even though

the expression be markedly improved, it is often very hard to reconcile them to the alteration. However, if a proper denture producing adequate restoration is worn for a week or so, the change for the better is so quickly noticed by the rest of the family that if the old plate were put in again they would not be pleased with it.

It seems to me that this work has brought me more satisfaction than any

I have ever done. To overcome difficulties which have usually been neglected, and to bring to a successful issue what was formerly a bugbear, should of course give one great pleasure, but more to me than all this is the joy I have felt in seeing my patients so well satisfied, and the knowledge that I have given them more than mere mechanical service.

40 EAST 41ST ST.

The Evolution of Orthodonty.

By WILLIAM K. GREGORY, Ph.D., New York, N. Y.,

ASSOCIATE IN PALEONTOLOGY, AMERICAN MUSEUM OF NATURAL HISTORY.

(Read before the Eastern Association of Graduates of the Angle School of Orthodontia.
New York, N. Y., January 26, 1918.)

MR. PRESIDENT AND GENTLEMEN:

FIRST, I must express my pleasure at being with you again this year. Perhaps you do not realize it, but we paleontologists are more or less isolated folk, working in our own corner here, and it is very seldom that we find people who are interested in a kindred line of work. It was therefore a great satisfaction to me to meet and know a body of men who are keenly interested in some of the same problems relating to the teeth which have engaged my attention in this museum.

I changed the title of my paper with the permission of the secretary, but must apologize for using the word "orthodonty" instead of orthodontia. Orthodontia no doubt is the name of your science, but in paleontology we have a great many words in use which end in "odonty," such as hypsodonty, the condition of long-crowned teeth, and brachyodonty, of short-crowned teeth. There are also many common English words which end in "y," like necessity, for instance, and matrimony. In fact, as matri-

mony is a state of wedlock, so, if you will pardon my levity, orthodonty is a state of interlock between the upper and lower teeth.

We have very definite foreshadowings of the orthodont relation of upper and lower teeth far back in geologic time. I have here [illustrating] a specimen of one of the mammal-like reptiles from the Triassic period of South Africa (*Cynognathus*). You will notice that the teeth are divided into incisors, canines, premolars, and molars, that the upper jaw overhangs the lower jaw or dentition, and especially that we have an alternation of upper and lower teeth, one lower tooth articulating with two upper teeth, so that there is a zig-zag relation. These three conditions—lateral overhang, alternation, and differentiation of the teeth—are likewise characteristic of all primitive mammals.

I am going to pass over long stretches of geological time, and come now to a period late in the Age of Reptiles, when the great dinosaurs flourished. There were then several distinct kinds of mam-

malian teeth, but we shall look only at one of these, that shown in the accompanying enlarged model of a lower molar (Fig. 1), because it represents the extremely primitive type which Professor Cope called "tritubercular," having reference to the three tubercles, or cusps, on the summit of the crown.

In the upper jaw there were also triangular teeth, and these upper and lower teeth interlock, or alternate, as shown in the diagram Fig. 2, A. We have a possible representative of that type ex-

posterior spur, or talonid. That is the beginning of an overlapping relation. We have first interlock, and then interlock plus overlap. In our terminology we call this anterior part the trigonid, or wedge-shape portion of the lower tooth, and we call this lower and posterior part the talonid. The trigonid is the part that fits between the upper teeth, while the talonid is the part that overlaps.

All this occurred during the Age of Reptiles; we had progressed at least that far. At the beginning of the Age of Mammals we find a further stage (Fig. 2, B). In the more primitive mammals of the Eocene period we find the normal tritubercular type, in which the overlapping relations are better developed, because the talonid has now widened considerably, so that there is a perfect alternation and interlock. The lower molars still fit into the spaces between the upper, but this posterior extension or talonid now overlaps broadly, so we have the stage of overlap well defined. This kind of lower molar was called by Professor Cope the tuberculo-sectorial type, the sectorial part being this wedgelike trigonid, while the tubercular portion is the talonid. The tuberculo-sectorial type is the ground plan of which we still find traces in modern carnivorous mammals, and even in herbivorous mammals, in primates, and in insectivorous mammals.

Fig. 3 illustrates the tuberculo-sectorial type in an Eocene carnivorous mammal (*Sinopa*), in which one readily sees these molar wedges and the talonids; one lower wedge fits accurately into the spaces between two upper wedges, while the talonids overlap on the crowns of the upper molars.

A very important feature of this arrangement is that the internal part of the upper tooth, the lingual part, fits into the talonid of the lower (Fig. 2, B). That relation holds throughout the normal mammals, and is equally true in our own teeth.

In this primitive stage the upper teeth are still wedge-shaped, or triangular, while in later, more specialized types they lose the triangular form. There are still spaces between the teeth, which

FIG. 1.

isting at the present day in the pouched mole *Notoryctes* of Australia. We see in this animal almost the exact relation between upper and lower molars that obtained in those far-off mammals of the Age of Reptiles. The lower teeth, as you see, are wedged in between the upper teeth. We have, then, this wedgelike stage in which the wedges of the upper jaw are pointed inward, and the wedges of the lower jaw are directed to the outer side. That was a fundamental relation in all the later, high types of mammalian teeth, and there is abundant evidence to show that to be a primitive condition for later mammals, no matter how it arose. It is an alternating and interlocking condition.

In the upper molar crowns there is at this stage chiefly a wedge, and very little else in this type of tooth. In the lower teeth we find a slight beginning of a

piercing or crushing points or cusps. The cutting edges become very impor-

FIG. 2.

Interlocking relations of upper and lower molars in three stages of evolution. Lower teeth in thick black lines. *A*, Late Mesozoic stage (based on *Kurtodon* and *Dryolestes*). Interlocking wedges. Lower molars with incipient talonids. *B*, Lower Eocene stage, based on many primitive placental mammals. Talonid of lower molars overlapping on upper molars. *C*, Upper Eocene and later stage in many grinding types. Antero-posterior diameter of molars increased, talonid of lowers widened, fitting between the now well-separated para- and metacones. Hypocones of upper molars overlapping into trigonid basin of lower molars.

Each molar crown of this kind of tooth contains two distinct parts. It contains first, cutting edges, and secondly

tant in later carnivorous types, especially the one on the posterior side of the upper tooth (metastyle shear). If we wish to

make a shearing tooth out of this triangular type, we simply elongate this posterior part (metastyle shear). On the other hand, if we wish to make a crushing tooth, we emphasize the cusps and broaden the crowns so as to obliterate the spaces between them.

EVOLUTION OF SHEARING TEETH.

Here is the first line of evolution coming from these primitive trituberculo-sectorial types. It is the shearing type, which is illustrated by this set of models showing the upper carnassial teeth in

FIG. 3.

Upper and lower molars of an Eocene carnivore (*Sinopa grangeri* Matthew).

two widely distinct races of ancient carnivora. The lower ones belong to the family of hyænodonts, while the upper ones belong to the family of the dogs. The primitive form is a triangular type. Simply by the emphasis of this posterior cutting shear in successive ages we see a triangular tooth transformed into a long shearing tooth. The tooth becomes narrower transversely, and greatly elongated antero-posteriorly. A posterior cutting shear is developed in many different races of mammals in this way. These two series, which were studied by Dr. Matthew of this museum, belong to totally different families, and yet the end results are very similar.

The evolution of shearing teeth, then, is one extreme. It is associated with a rigidly vertical, or orthal movement of the jaw. Here, in an ordinary cat [il-

lustrating], you find this shearing dentition strongly developed. In the upper carnassial here is the shear, and here is the inner cusp greatly reduced. In the lower molar two of the cusps (protoconid and paraconid) of the trigonid become shearlike; the third (metaconid), together with the talonid, disappears. The jaw muscles in these shearing types are adapted to pull the jaw straight up, so that the sides of the teeth shear past each other. That is a great principle of shearing teeth and orthal jaw movement; the edges and sides, and not the crown, are the important functional parts. This line of evolution takes place independently in different families of mammals. Here [illustrating] is a carnivorous marsupial, where this shearing type of dentition is developed. And here is a common opossum, which is still in a very primitive stage.

In an opposite line of evolution the emphasis is all laid on the breaking and crushing parts. The points or cusps become predominant, and the overlap of one part on another becomes emphasized, so that it is now the surfaces of the crowns that oppose each other, rather than the sides. A good example of that is seen in the bear, where we have great flat crowns working one against the other, with very little of the cutting function left. This involves the filling out of the space between the two teeth. We no longer find these spaces, but we have now the wide overlap of the lower teeth upon the upper, with a great emphasis of the bruising and crushing parts. That kind of evolution is carried to an extreme in the dentition of the sea-otter, the molar teeth being adapted for crushing and bruising the shellfish that the animal feeds on. The contact is more on the surface than on the sides of the crowns, and the cutting blades have been entirely sacrificed. We have various intermediate stages to connect this with the stem type; in fact, all the diverse cutting and crushing molar types are derived from the primitive wedgelike type.

Thus one may say that the crushing type is a degenerate derivative of the

tritubercular type; the teeth simply lose their sharp edges and the points become blunt. There is a hingelike joint of the lower jaw, and all the muscles are adapted for pulling the jaw straight up.

EVOLUTION OF CRUSHING AND GRINDING TEETH.

One very important feature in the evolution of both the crushing and the grinding types (the next stage to be considered) is the change from a wedge shape to a quadrangular crown. This upper molar of a raccoon [illustrating] has the primitive triangular pattern, but at the posterior internal angle there is also a swelling growing out to form another cusp. This is called a hypocone, according to Professor Osborn's system. We find that it tends to obliterate the triangular pattern. The development of a hypocone takes place not only in pure crushing types with orthal jaw motion, but also in grinding types, where lateral motion is possible.

We come, then to the grinding types. The hypocone or posterior cusp becomes greatly developed, so that the primitive triangular symmetry is lost, and the crown becomes quadrangular. Another feature of grinding types is that the cusps themselves lose their primitive character, and become modeled into various crests and ridges. Here, for example, is a primitive form of herbivorous mammal (*Phenacodus*), but there is now but little suggestion of the former triangular contour of that tooth. Every stage can be traced, however, in the development of this postero-internal cusp, and it is no doubt a secondary feature. Notice that these cusps are now modeled into low ridges that stretch obliquely across the crowns. These crests and the crescents of other grinding types function in connection with the swing of the mandible from side to side.

In this tapir the four cusps of the upper molars are united into two cross crests, and in the lower molars we have the same union of opposite pairs of cusps. That is associated with a movement of the jaw that is quite different from the

vertical, orthal movement of primitive tritubercular types. It is called the ental movement, because it is from the outside to the center of the tooth. This ental swing of the jaw is clearly deducible from the character and details of the worn teeth. The external pterygoid muscle is always well developed in these types. Here is a fossa for the insertion of that muscle on the inside just below the condyle. When the external pterygoid muscle of one side is contracted the condyle moves forward in the glenoid socket of the same side, and the jaw projects toward the opposite side. Thus pure grinding types are associated with the development of ridges and cross crests, and with a more less lateral swing of the mandible.

Even the most complex of the grinding patterns have been traced back to the more primitive quadrangular types, and eventually to the tritubercular wedge-like type.

In this diagram (Fig. 2, C) I have endeavored to express the linking of opposite cusps into ridges and the filling out of the contour of the crowns, now become quadrangular in form, with correlated obliteration of the spaces between the successive molars, and the relations of the upper and lower crests, in a generalized grinding type of molars.

Having reviewed the general adaptive radiation of the primitive tritubercular molars into the cutting, crushing, grinding, and mixed types, we may review the evolution of the molar patterns in the primates. The primates exhibit a wide range of adaptive radiation, from primitive tritubercular types to elaborate crested types, and they vary from an orthal movement of the jaw to a marked ental movement. As illustrations of the primitive primate type I may exhibit Figs. 4 and 5. Here are the upper and lower molar teeth of two genera of primates from the Eocene of Wyoming. They are triangular in form, and very primitive. The lower teeth also are of the primitive tuberculo-sectorial type, with a high trigonid and a low and broad talonid. (See Fig. 5.) You can trace many variations in form from this

primitive type. Here [illustrating] is the actual history of that type through ascending levels in a single family; the latest type has lost the triangular symmetry, and has become quadrangular in

lemurs which preserve the primitive tritubercular type with relatively little modification. In another lemur, however (*Hapalemur*), the molar cusps are becoming round and blunt, and are losing

form. We can follow the evolution with great definiteness, and at the same time trace the change from a more vertical movement of the jaw to an oblique side swing.

Here [illustrating] are several recent

their originally sharp-edged character. That animal is tending to sacrifice the shearing function, and its molars are becoming more or less of the crushing type. In *Propithecus*, another lemur, the molar crowns are becoming crescentic,

Names of the molar cusps in man (A, B) and in a primitive Eocene primate (*Pelycodus*, C, D). This system of names was invented by Professor Osborn in 1888, and is now used all over the world by paleontologists. A, Second left upper molar of a Kaffir. ($\times 3:2$) B, Second left lower molar of an Australian black. ($\times 3:2$) The human lower molar has lost the paraconid. An accessory cusp (6) is developed in some anthropoids and men. C, Second left upper molar of *Pelycodus trigonodus*, a Lower Eocene primate. ($\times 3:1$) D, Second left lower molar of the same. ($\times 3:1$)

and the jaw swings obliquely sidewise. The side swing of the mandible is also shown in this South American howler monkey (*Alouatta*). The jaw sweeps from the outside inward, just as does the jaw of the tapir, and one can see clearly from the character and articular relations of the upper and lower crowns how the jaw works. That is also borne out

ries, which culminates in man, we find a mixed type. It is neither a pure crushing type, nor a shearing type, nor altogether a grinding type. The jaw is capable of considerable side swing, but the molar pattern is really rather primitive, even in the most progressive anthropoid, which is the gorilla. In modern man the molar pattern is partly retrogressive.

FIG. 9.

Interlocking relations of the upper and lower cheek teeth. A, *Polycodus trigonodus*, a Lower Eocene lemuroid, with primitive molar patterns. B, Gorilla sp. C, *Homo sapiens* (Australian Black). The premolars in this specimen are irregular in position. In this position the jaw projects toward the right. D, *Homo sapiens* (Negro). When the jaw projects toward the right, the upper and lower molars in this specimen assume an end-to-end relation.

by the form of the condyle and of the glenoid fossa, which permits considerable side swing. The ridges and cusps in this specimen are very much worn off, but they are all clearly homologizable with the original primate type shown in Fig. 4. In the macaque-baboon series the four main cusps of each molar are linked in opposite pairs, which tend to form cross ridges.

When we come to the anthropoid se-

In the orang and chimpanzee we find the ancient tritubercular symmetry of the upper molar crown disguised by this hypocone, which buds out at the postero-internal corner. Similarly in this lower molar we find the tuberculo-sectorial pattern much disguised, but one can still distinguish the remnant of the trigonid, which has lost the paraconid, and one can see that the talonid has become very large and wrinkled.

Here [illustrating] (Figs. 6 and 7) is the milk dentition of the chimpanzee. All that posterior part of the lower molar is the talonid, which is now greatly enlarged, and overlaps widely the upper molar. The result of this overlapping tendency is seen in the human dentition, producing the occasional end-to-end relation of the upper and lower molars with which you are all familiar.

This [illustrating] is a model of the skull of a fossil man (*Homo heidelbergensis*) from the early Pleistocene period in Europe, as reconstructed by Professor McGregor. It has the human dental arch, although it is estimated to be about 250,000 years old. In the molars we see none of the primitive shearing and cutting action of the primitive primate type, but instead of a chiefly orthal movement of the jaw we have now more of a mill-like action, a more or less sweeping or grinding action which has polished off or worn down the separate cusps into a fairly even plane. One can readily homologize the molar cusps by comparison with the chimpanzee.

This grinding motion no doubt followed upon the reduction of the canines and the retraction of the lower canines; it accompanied the shortening and curving of the dental arch in man. I need not speak further of the changes in the front teeth, with which you are all familiar. The dwindling lower canines have withdrawn from their primitive position in front of the upper canines and are now in a secondary position, which occurs in the human race alone. This general pattern of the arch and of the molars is eminently adapted for the more or less rotary motion of the jaw.

This diagram (Fig. 9) shows the relation of the upper and lower teeth in successive stages of primates. In the lower Eocene primates we have an interlocking of the upper and lower molars in the primitive tritubercular fashion. (See

also Fig. 5.) In the gorilla (Fig. 9, B) and other anthropoids we find a great overlap of the lower molars upon the upper, the talonid of the lower teeth being greatly enlarged, and the trigonid reduced. In the more primitive human types we still get this combined interlocking and overlapping of the upper and lower teeth, but in some cases the overlapping parts become greatly emphasized, while the primitive interlocking part (trigonid) is further reduced. Also we still have the fact that the protocone of the upper fits into the talonid basin of the lower teeth.

In conclusion, therefore, I would emphasize the fact that the human dentition is simply a special modification of the primate series, and that these fundamental interlocking and overlapping relations, which you in your practice encounter daily, may be traced back to the beginning of the Age of Mammals.

On Healthy and Diseased Conditions of the Alveolar Processes of the Jaws.

By A. HOPEWELL-SMITH, L.R.C.P., M.R.C.S., L.D.S., Philadelphia, Pa.,

PROFESSOR OF DENTAL HISTOLOGY, HISTOPATHOLOGY, AND COMPARATIVE ODONTOLOGY, THOMAS W. EVANS DENTAL INSTITUTE SCHOOL OF DENTISTRY, UNIVERSITY OF PENNSYLVANIA.

(Read at the meeting of the Eastern Association of Graduates of the Angle School of Orthodontia, January 26, 1918, held at the American Museum of Natural History, New York, N. Y.)

INTRODUCTORY.

HUMAN teeth are attached to the skeleton by means of a fixed, immovable joint or articulation, in which their conical root portions are inserted, like nails driven into a piece of wood, into sockets called the alveoli of the alveolar processes of the maxillæ and mandible. "Alveolus" means a hole. Contrary to the generally accepted but unanatomical view, the teeth are firmly fixed, at all events normally, into the bone. An apparent movement in four directions can be noted by the use of finger and thumb, but the application of pressure by the digits gives rise to a false and erroneous impression. There is no appreciable movement of the teeth in their articulations. This immobility can be noted and verified by examining any collection of human skulls. The loose teeth found in such skulls have been loosened by disease.

THE ARTICULATION OF THE TEETH IN THE VERTEBRATES AND IN MAN (GOMPHOSIS).

The articulation of the teeth in man is designated gomphosis, a purely Greek word meaning "a bolting or nailing together." It is a variety of the class of articulations termed *synarthrosis*, which denotes an immovable joint. In the *synarthroses* the articulating surfaces of

the bones are in almost direct contact, being joined by a thin intervening layer of fibrous or cartilaginous connective tissue. Examples of these are found in the joints between the facial and cranial bones, with the sole exception of the temporo-mandibular articulation.

There are four varieties of *synarthrosis*, viz: (1) *Sutura*, as in the skull bones, which are fastened together by fibrous tissue called sutural membrane; (2) *schindylesis*, in which one bone fits into a groove in the other; (3) *synchondrosis*, where the connective medium is cartilage; (4) *gomphosis*, comparable to that of a tenon or peg of one bone being received into the mortise or cavity of another. This latter obtains in the dental articulation of man and in the higher vertebrates.

Among the lower vertebrates, the fish present several different means of attaching the teeth to the jaws. There may be, for instance, a ligamentous articulation, an osseous ankylosis to the so-called "bone of attachment," a "hinge" form, and a gomphosis as in man. Gomphosis in fish may be modified into a true fibrous gomphosis, a double gomphosis, and a bony gomphosis. Amongst reptiles generally, the method of union is by bony ankylosis; but in the crocodile sockets are found.

It is important to bear these facts in mind when considering the methods of attachment of the human teeth to the

jaws, for they throw considerable light on problems relating to the subject of this communication.

THE RELATIONSHIPS, STRUCTURE, AND FUNCTIONS OF THE PARTS.

Of all the structural elements in the teeth associated with their articulation, the bony socket, the alveolo-dental periosteum, the cementum, and the gingival tissues are of the highest importance. It is necessary to discuss briefly and succinctly the normal relationships, structure, and functions of these several parts as they occur in man.

I. THE CEMENTUM.

The cementum may be regarded structurally as merely a dense, hard shell of calcified material, homologous with that kind of tissue which covers the surfaces of bones generally, known as the peripheral lamellæ of bone. It measures only 175 to 250 microns (140th to 100th of an inch) in thickness; it contains, in spite of erroneous beliefs, no lacunæ and canaliculi, no Haversian systems, no bloodvessels, and no nerves. Fully calcified, well-formed tissue consists of a structureless matrix, but often its make-up is revealed in the presence of incremental lines, perforating canals and fibers, and Sharpey's fibers in their containing tubes.

Its relationship to enamel at the necks of the teeth is such that normally the two tissues are in absolute contact, meeting edge to edge. This occurs in 30 per cent. of cases examined for the purpose. Enamel overlaps cementum in 0.5 per cent. of cases, and cementum overlaps enamel in 60 per cent. of cases. According to Choquet,⁽¹⁾ in 27.5 per cent. of cases there is a breach of continuity between the two tissues and a minute portion of the dentin is actually exposed.

The function of cementum is to serve as a dense, non-sensitive, inert covering for the dentin of the roots of the teeth (as possessing no nerves it cannot generate nervous impulses), and affords strong attachment by means of Sharpey's

fibers to the principal fibers of the periodontal membrane.

II. THE ALVEOLO-DENTAL PERIOSTEUM.

The alveolo-dental periosteum is a modified form of periosteum which forms the soft vascular covering of bones. It differs by being placed between two hard, unyielding walls, cementum on the one side and alveolar bone on the other. It varies in width from 0.4 to 0.6 mm. (about a 50th of an inch), and is composed of bundles of strong white connective fibers, no elastic fibers being demonstrable. It has a scanty vascular and nervous supply. Osteoblasts and epithelial "rests" are also found, the former in great numbers, the latter sometimes altogether absent. A gingival gland and a lymphatic system in the periodontal membrane exist only in the imagination of incompetent observers.

Its functions are important. They are fourfold, viz, physical, sensory, nutrient, and formative.

A. (a) It affords a strong fibrous attachment to the roots of the teeth. (b) It provides a layer of soft material in which bloodvessels and nerves ramify without risk of damage or permanent injury by mechanical shock. (c) It may act as an apparatus for diminishing the force of compression with an opposing body, whether it be dental in origin or otherwise.

B. It is sensory, through its nerve supply—a beneficent arrangement on the part of nature.

C. Like the periosteum of other bones, it possesses a certain amount of trophic or nutritive influence on the alveolar walls of the dental sockets.

D. It is formative, in that it is capable of very frequently providing, by virtue of its osteoblasts, fresh tissue (hyperplastic cementum) on its inner aspects: which is an evidence of its reaction to injury, whether it be of a traumatic, chemical, or bacteriological character.

III. THE GINGIVAL TISSUE.

The gingival tissue includes those soft, dense structures which envelop the alveo-

lar processes of the jaws. Consisting of mucous and submucous tissue, it exhibits on its free surface the stratified squamous epithelium common to the other parts of the mucous membrane of the oral cavity; and, beneath, numerous closely interwoven bundles of fibrous connective tissue arranged in the form of simple and compound papillæ, and containing also adipose tissue, mucous glands, bloodvessels, nerve fibers, and sometimes the so-called "glands" of Serres.

The gingival tissue is attached to the cementum at the necks of the teeth, and blends insensibly with the fibers of the periodontal membrane. The gum over the interdental septa is of similar structure.

On account of its smooth surface the gum acts as a protective covering for the alveolar processes of the jaws—to the periosteum of which it is also nutritive through its blood supply. It fills up the interdental spaces, and thus largely prevents the lodgment of food in these situations. By means of its mucous glands it has some share in the lubrication of the mouth. It furnishes bloodvessels to the periodontal membrane.

IV. THE ALVEOLAR PROCESSES.

The alveolar processes are constructed of hard bone which is neither typically compact nor cancellous. The external alveolar plate is thinner and terminates in a sharper edge than the internal alveolar plate. In man the structure of the bone is far from being typical, as will presently be shown.

Functionally, the alveoli serve to support the teeth. A fact of primary importance is that the bony alveoli grow up with and are molded, during developmental periods of growth, around the roots of the teeth. "Teeth do not come down and take possession of sockets more or less already made and pre-existent, but the socket is subservient to the position of the tooth; for wherever the latter may chance to get, in eruption, there its socket will be built up around it."⁽²⁾ In short, the position of the tooth determines that of its socket.

SIGNIFICANCE OF THE "LAMINA DURA" AND THE GINGIVAL TROUGH.

Immediately surrounding the periodontal membrane is the lamina dura, an infinitely thin shell of compact bone, well displayed in good radiographs of the parts. The lamina dura becomes easily and at an early period affected by disease, undergoing halisteresis or decalcification, and also lacunar absorption, and thereby diminishing the firm dental attachment to the alveolar bone. This degeneration is greatly predisposed to by the contents of the gingival trough. The gingival trough at the cervical margins of the teeth is bounded externally by the oral epithelium, internally by enamel, and below by its firm union with the cementum. Its depth, even in children, is from 2.3 mm. to 4 mm.

It contains, as a normal condition, epithelial debris, phagocytes, and always countless numbers of bacteria, chiefly those belonging to the *Streptococcus* and *Micrococcus catarrhalis* groups.

ATROPHY OR PHYSIOLOGICAL ABSORPTION OF THE BONE.

The alveolar bone is a particularly transitory and unstable structure. Osseous tissue in general is frequently undergoing changes, from the time of its first formation. And these changes are most pronounced in the alveolar processes of man.

It is a diploëtic tissue similar in almost all points to that cancellous tissue which intervenes between the two plates of the cranial bones, such as the parietal. The histological features of the alveolar processes vary according to their position. Thus, in that of the canine fossa, even in subjects of ten and a half years, the bone is scantily supplied with Haversian systems, portions contain no lamellæ, and but few lacunæ and canaliculi, the matrix being coarsely granular. Many of the lacunæ are abrachiate.

The lattice-like character of the bone of the interdental septa corresponds with the spongy bone of the carpus and tarsus, and expanded ends of the tibia and fe-

mur. The lamellæ are disposed in lines parallel with the edges of the large medullary spaces in the bone, and in the alveolar processes the cancellous spaces run longitudinally in the same direction as the long axes of the teeth. The Haversian systems and lacunæ are marked, and the thin peripheric lamellæ are slightly denser than in other parts. The terminal free rim, however, is so thin that there is little, if any, room to accommodate any medullary tissue or Haversian canals. It has thus an impoverished blood supply, and its vitality is necessarily very low.

The significance of this fact will be at once appreciated when general disturbances of the circulatory system, such as anemia or hyperemia, as well as when general marasmus or marantic or senile changes are beginning to become manifest.

The result is absorption of this terminal edge or rim—(1) physiological in the case of old age (an elastic term not necessarily governed by the number of years of the individual), and (2) pathological, due to disease of the neighboring parts. Most animals *in ferâ naturâ* lose their teeth by shedding, through this physiological absorption of their sockets: the same is true in man, too, but in the latter the process is greatly aggravated and accelerated by incipient disease. The effects of civilization have not only been felt by the teeth, but by their sockets also.

The reasons for this predisposition for absorption, or atrophy, or wasting on the parts of the sockets of the teeth are as follow:

(1) The unique character of the osseous tissue, to which reference has been already made.

(2) The inadequacy of the blood supply, with consequent tendency to malnutrition.

(3) The absence of muscular attachments.

(4) The practically functionless character of the articulation. Bone exists primarily for the attachment of the muscles. In the jaws a few fibers only of the buccinator may be attached to the

molar regions of the maxillæ and mandible.

EVIDENCES OF SIMILAR CONDITIONS IN THE JAWS OF MAN AND THE LOWER ANIMALS.

Not only does bone undergo this physiological absorption, but dentin and cementum do, too.

(1) This is noted immediately on the examination of a vertical section of the jaws of a mammal, *e.g.* a kitten before the deciduous teeth are shed; it is also exemplified in the teeth of animals which have a polyphyodont dentition, as the crocodile.

(2) The same process occurs in man. The apical portions of the roots of deciduous teeth become painlessly absorbed by the working of natural laws, even if they be not followed by permanent successors. Radiographs show this fact.

In these cases, histologically the process would appear to be identical with pathological conditions. The hard parts are removed by the agency of myeloplaxes, or osteoclasts, and very frequently the process of repair may be seen going on side by side with the process of absorption.

(3) If skulls of children of about four or five or six years be examined, the phenomena associated with the shedding of the deciduous teeth and their sockets can be followed very well. There is here a physiological absorption of bone, the immediate effect being the thinning of the tissue by a method similar to that of osteoporosis.

Thus there is an entire absorption and complete loss of the sockets of the deciduous teeth occurring in a normal painless way. Writing about this absorption Tomes⁽³⁾ says: "The alveolar portion of the jaw, that which lies above the level of the inferior dental canal, is developed around the milk teeth; when they are lost, it disappears, to be re-formed again for the second set of teeth, and is finally wholly removed after the loss of the teeth in old age."

(4) The skulls of adults show a similar wasting of bone around the cervical

radicular portions of teeth. They frequently demonstrate osseous atrophy over the labial surface of the mandibular canine, and over the palatal aspect of the palatine root of the maxillary molar, as well as in other places.

(5) The changes undergone by the bone of the mandible are well known. Again to quote Mr. Tomes:

As the jaw undergoes increase in size, large additions are made to its surface by deposition of bone from the periosteum, necessarily lengthening the canal. The additions to the canal do not, however, take place quite in the line of its original course, but in this added portion it is bent a little outward and upward. If we rasp off the bone of an adult jaw down to the level of this bend, *a process which nature in great part performs for us in an aged jaw*, or if instead we make due allowance for the alteration, the mental foramen becomes an available fixed point for measurement.

The manner in which the jaw is formed might also be described as wasteful; a very large amount of bone is formed which is subsequently, at no distant date, again removed by *absorption*; or we might compare it to a modeling process, in which thick, comparatively shapeless masses are dabbled on, to be trimmed and pared down into form.

To bring it more clearly home to the student's mind, if all the bone ever formed were to remain, the coronoid process would extend from the condyle to the region of the first premolar, and all the teeth behind that would be buried in its base: there would be no "neck" beneath the condyle, but the internal oblique line would be a thick bar corresponding in width with the condyle. It is necessary to fully realize that the articular surface with its cartilage has successively occupied every spot along this line; and as it progresses backward by the deposition of fresh bone in its cartilage, it has been followed up by the process of absorption removing all that was redundant.

On the outer surface of the jaw we can frequently discern a slight ridge, extending a short distance from the head of the bone; but if the prominence were preserved on the inner surface, the inferior dental artery and nerve would be turned out of their course. We have thus a speedy removal of the newly formed bone, so that a concavity lies immediately on the inner side of the condyle; and microscopic examination of the bone at this point shows that the *lacunæ of Howship*,

those characteristic evidences of absorption, abundantly cover its surface, showing that here at least absorption is most actively going on.

In the same way the coronoid process, beneath the base of which the first, second, and third molars have successively been formed, has moved backward by absorption cutting away its anterior, and by deposition adding to its posterior surfaces.

In old age, concomitantly with the diminution of muscular energy, the bone about the angle *wastes*, so that once more the ramus appears to meet the body at an obtuse angle. But all the changes which mark an aged jaw are the simple results of a *superficial and not of an interstitial absorption*, corresponding with a wasting of the muscles, of the pterygoid plates of the sphenoid bone. [The writer's italics.]

(6) Two further instructive examples from comparative anatomy may be given. In *Batrachia*, e.g. the frog, the teeth are attached by their bases and external surfaces to a groove in the jaw, having the exterior wall higher than the inner, and also having on their outer side a new osseous development, which slightly extends over the outer side of each tooth. The deficiency on its inner aspect is supplied by a bony pillar, which disappears when the tooth is shed, a new column being developed for the succeeding tooth. But an even more interesting fact is observed in the mouth of the eel. Here the teeth are fixed to the jaws by means of a "bone of attachment." When the teeth are shed, the bone of attachment is shed also, being removed from the body of the jaw itself. This is effected by means of large multinucleated giant cells, which leave the surface of the bone scalloped out into Howship's foveolæ. It is often impossible to decide, under the microscope, whether the tissue which is being absorbed by these myeloplaxes is normal or diseased, so closely identical are the two processes.

(7) It is certain that the free alveolar edges of the jaws of man begin to disappear at a very early age. Radiographs, for instance, show the commencement of the absorption of the bone around the roots of the deciduous incisors in the normal mouths of children.

The commencement of the atrophy can be noticed in the incisor as well as the molar region. The laminae duræ remain intact except at the gingival margins.

Examples need not be further multiplied; the truth is so apparent.

(8) Finally, a quotation from two eminent authorities on general and special pathology may close this portion of the subject. Hektoen and Riesman⁽⁴⁾ write:

It is generally believed that anemia of bone favors absorption and hinders apposition, and it may be one of the factors in these forms of atrophy. The atrophy may be concentric or eccentric. It begins, as a rule, at those points that are free from muscular attachments. In the calvaria the bone becomes thin, granular, and finely porous, especially in the temporal regions; as atrophy occurs in the external table, the internal may become rough from the production of new bone. In the maxillæ the alveolar process may disappear completely.

PATHOLOGICAL CHANGES IN THE OSSEOUS AND FIBROUS TISSUES INDUCED BY MECHANICAL FORCES.

Regarding this aspect of the subject, current literature furnishes considerable data, to be found in the writings of Angle,⁽⁵⁾ Sir Arbuthnot Lane,⁽⁶⁾ Henry Baker,⁽⁷⁾ Lawrence Baker,⁽⁸⁾ Bogue,⁽⁹⁾ G. V. I. Brown,⁽¹⁰⁾ Buckley,⁽¹¹⁾ Case,⁽¹²⁾ Cryer,⁽¹³⁾ Hartzell,⁽¹⁴⁾ Hawley,⁽¹⁵⁾ Keith,⁽¹⁶⁾ Ketcham,⁽¹⁷⁾ Körbitz,⁽¹⁸⁾ Landsberger,⁽¹⁹⁾ Lischer,⁽²⁰⁾ Noyes,⁽²¹⁾ Ottolengui,⁽²²⁾ Pullen,⁽²³⁾ Spiller,⁽²⁴⁾ Summa,⁽²⁵⁾ Talbot,⁽²⁶⁾ Young,⁽²⁷⁾ etc. Out of this mass of evidence and observation there would appear to emerge a general belief that—

First: If slight force is applied, an absorption of the bony tissue on the side away from the point of delivery, and the slow development of osseous material on the side next to it, would occur, the absorption would be similar in its phenomena to the physiological absorption just noticed, and the deposition of bone would be accomplished normally by the osteoblasts which clothe in enormous numbers the surface. Some writers claim to have demonstrated bending of the bone.

Secondly: If strong force is applied, an inflammatory condition of the periodontal membrane is undoubtedly induced, which leads to loosening of the teeth, a hyperplastic condition of the cementum, and a local circumferential osteomyelitis of the alveolar process.

Thirdly: If the strongest force is applied, as in the operation of immediate regulation, a green-stick fracture of one of the alveolar plates is brought about, and an ensuing inflammation of all the tissues is involved.

PATHOLOGICAL CHANGES INDUCED BY DISEASE.

Local anemia is often produced by disturbances of the vaso-constrictor and vaso-dilator systems of the vessel walls. The arteries become narrow, and this increases the resistance to the blood current. The blood reaches the capillaries under low pressure. The capillaries contract and the total quantity of blood in a given area is diminished. Macroscopically the signs are paleness of the tissues; but on account of the dense covering of the gingival region by means of the stratified squamous epithelium, the blanching of the parts can generally be recognized only by comparison with healthier localities.

Anemia favors absorption, as has already been pointed out. The make-up of bone is influenced by two functions: static, *i.e.* the lines along which pressure is exerted, and mechanical, *i.e.* the direction in which muscles pull. With regard to the first, which applies only to the subject under consideration, the whole of the internal structure of the alveolar process is changed.

Absorption occurs either in the form of lacunar destruction by means of giant cells, or by a method of decalcification termed halisteresis, or by so-called perforating canals filled with vascular connective tissue which passes across the lamellæ from one Haversian canal to another, as demonstrated by Pommer.⁽²⁸⁾ Atrophy due to pressure is very common in bones generally; it can be produced by continuous pressure exerted by slowly

growing tumors, by contracting cutaneous cicatrices, or by inflammation as in the maxillary sinus and the middle ear, etc. Senile and marantic atrophy occur in young and old who suffer from marasmus or general wasting due to various chronic diseases or malnutrition.

Hyperemia favors a consolidation of bone tissue or hyperplasia, in which the tissue elements are increased in large numbers. If it remains only as a hyperemia, and does not pass on to acute inflammation, the condition continues stable, and is therefore desirable: but unfortunately it leads to absorption of bone and cementum. True bony union or ankylosis of cementum and alveolar process occurs only rarely, about a dozen cases having been recorded so far.

The result of a stomatitis or gingivitis, simple or purulent, pyorrhœic or non-infective, acute or chronic, is generally to produce an inflammation of the periodontal membrane, which has as its sequelæ hyperplasia of the cementum and absorption and disappearance of the bony socket.

These are the probable accompaniments of tooth movement, but as yet our knowledge of this subject remains very incomplete, and one cannot dogmatize on the matter until more sections of the teeth *in situ* which have been moved by mechanical means have been made, examined, and studied.

Radiolucency of Chloro-percha in the Radiograph.

By W. CLYDE DAVIS, M.D., D.D.S., Lincoln, Nebr.

WHILE doing some research work relative to root-canal fillings and focal oral infection, I was impressed by the large number of root-fillings I had personally placed which showed a healthy apical region with the root-filling apparently extending only one-half or two-thirds of the way to the apex, the remaining one-half or one-third showing as though there existed an entirely unfilled canal, easy of access, yet small.

I therefore made the following experiment, which I would advise every radiographer to perform, in order to prove my findings.

I prepared four small straight root-canals, as found in lower centrals. I opened them with a small reamer until the broach would protrude slightly through the apical end. I flooded the canals with eucalyptol, then pumped into the canals chloro-percha, as used by dentists generally for the past thirty years. This was pumped into the canal until it formed in a ball beyond the apex. A canal point was forced into the canal one-half the length of the canal, the

point having been previously measured and cut to one-half the length of the root. The excess chloro-percha was then wiped off the end of the root.

These roots were then lightly waxed to the face side of a film and exposed full time, at the usual distance. The film showed nothing in the apical half of the roots, while the canal point showed up clearly for the portion it occupied.

The above is easily proved, and prompts me to ask, How much does the radiograph show us about the presence or absence of root-fillings placed during the past thirty years?

I am at present using a radiopaque chloro-percha made by adding 8 grains of bismuth subnitrate to each dram of chloroform before dissolving the gutta-percha.

Dentists and radiographers should try this experiment, and think a bit before they make a diagnosis of "No root-filling" from a roentgenogram in which the apical third of a root-canal appears to be unfilled.

OLIVER BLDG.

CORRESPONDENCE

The Naval Dental Surgeon at Work.

TO THE EDITOR OF THE DENTAL COSMOS:

Sir,—Please allow me to extend my personal thanks for the support that you are giving the Naval Dental Corps in regard to the legislation now before Congress. May I take this as an opportunity to say a few words on behalf of the corps?

The field of operation for the naval dental surgeon is an unusually large one—much more so than is realized by the greater number of people. On our larger ships we find from 1000 to 1500 men. Considering the rapidity of the growth of the navy you will readily see that the greater part of these men are new to the service. Many of them are boys between the ages of seventeen and twenty-one years—in other words, just at the point where they start to pay attention to the teeth and oral cavity—and a large per cent. of them have never before had any dental work done for them.

Take my own work, for example: I have about 1200 men under my care, and find that there is all the work that I can take care of in the allotted hours—namely, from 8.30 A.M. to 4.30 P.M. In the mornings from 8.30 until 9.00 we hold what we call “sick call.” At that time I see all new patients and those old ones who have either missed a previous appointment or have been dismissed for any period under treatment. The rest of the day is divided into fifteen- and thirty-minute periods for appointments. An appointment card is given to the patient and this excuses him from any duty during the stated period. We manage to see an average of 12 patients every day, and find that by this procedure we are able to complete about forty cases each month.

By a completed case I mean one in which all the work I am permitted to do has been finished and the patient's mouth left in an aseptic condition.

When I was first assigned to this ship they had been without the services of a dental surgeon for nearly a year; consequently I found a number of very bad cases. The sick list at that time was very large. Now, having been here nearly nine months, it is with a great deal of satisfaction that I note a marked decrease in the size of the sick list, and a better appearance of the men in general. Of course the dental work may not be at all responsible for the change, nevertheless I feel that cleaning up the mouths of the men and giving thorough instruction in oral prophylaxis has had a noticeable effect for the better.

Some of my most interesting cases have been fractures of the mandible, and so far I have had very good success in treating them. I have also implanted natural teeth in several instances, and while it is too early to judge of results, I am inclined to think they are satisfactory.

I have tried to point out the importance of our work, and to show the results that are being derived from it, and I am sure that my case is similar to that of every dental surgeon in the service. Is not a man who is *free from all infectious or painful teeth* a much better man to have guarding our seas than one who is continually suffering from these conditions?

Yours truly,

E. W. WILLETT,
Dental Surgeon, U. S. N.

U. S. S. “Florida,” Feb. 28, 1918.

PROCEEDINGS OF SOCIETIES

Eastern Association of Graduates of the Angle School of Orthodontia.

Regular Meeting, held in New York City, Saturday, January 26, 1918.

(Continued from page 334.)

AFTERNOON SESSION.

(Continued.)

THE next item on the program for the afternoon session was the reading of a paper by WM. K. GREGORY, Ph.D., New York, N. Y., entitled "The Evolution of Orthodonty."

[This paper is printed in full at page 417 of the present issue of the COSMOS.]

DISCUSSION.

Prof. H. F. Osborn. Dr. Gregory is a very modest man. His principal discovery, I might say, is in the intimate mechanical and spatial relations of the upper and lower cusps to each other, and the fact that the spatial relations have remained unchanged from the very beginning. A projection of the lower crown upon the upper crown will show that the protocone always has exactly the same spatial position with relation to the hypocone spur projecting from the lower teeth. The position of the protocone is absolutely constant throughout the entire mammal series. Dr. Gregory has made a very special study and a distinct contribution to odontology in this discovery.

So far as the general theory of the teeth goes, Dr. Gregory has given us an epitome of all the work that has been done since 1880, when Cope discovered the principle of trituberculy.

It always has seemed to me one of the most wonderful things in all nature that the primitive triangular form has furnished the material, so to speak, on which every possible variety of tooth is evolved, from the highly effective shearing teeth of the carnivora to the tubercular teeth of man and the wonderful grinding teeth of horses; that through the entire series we can always select a cusp and be absolutely sure of the history of that cusp going back to the most remote period that we can find.

It is rather interesting to note that while Dr. Gregory and I have been working together, we have reached opposite views as to the theory of the origin of the primitive triangle, but this has never produced the slightest disharmony between us. Violent personal differences sometimes arise from such differences of opinion, but we are perhaps better friends than ever. It remains to be seen from future paleontological discovery which opinion proves to be correct. As the evidence stands at present, I think the odds are rather in favor of Dr. Gregory's opinion.

Dr. Milo Hellman. Before offering any remarks on the discussion of Dr. Gregory's paper, I wish to congratulate the society upon the honor of having present at this meeting a man whose name is most intimately associated with the evolution of teeth. I refer to Pro-

fessor Osborn. It is to be regretted that the dental profession has failed so far to take cognizance of the fact that Professor Osborn has given the scientific world a terminology of the cusps of the teeth which is not only clear, descriptive, and concise, but also of great evolutionary significance. It is my sincere hope that some day we shall realize its value, and introduce its usage in all scientific dental literature.

Dr. Gregory has given us the evolution or traced the relationship of the cusps of the upper and lower teeth. He has shown that what we term normal occlusion, or normal mechanical relationship of the teeth, really dates back over a considerable stretch of time. Up to the present under normal conditions we can see that we still have a plan that probably has existed for millions of years. In modern man there is a tendency manifesting itself which threatens to upset this plan. The causes thereof, though not quite definitely ascertained, may be of evolutionary, phylogenetic, ontogenetic, or pathologic origin. The result, however, is found to be quite clearly confined to the development of the jaws as indicated by the malrelationship of the teeth. So far, the one actual diagnostic factor in orthodontia is the recognition of the disturbance of development by the malrelation of the cusps of the teeth. The aim of orthodontia today is the restoration of occlusion and interference with maldevelopment. It is therefore of great importance to watch and observe whether the work accomplished by the orthodontists is merely restorative, or whether it has some prophylactic value: *i.e.* whether it may be possible to intercept or interfere with the present tendency of malocclusal occurrences in coming generations.

I also wish to direct the attention of those present to the fact that in order to justify our work on scientific grounds it is necessary to get the viewpoints of such men as we have with us today. Also, that in order to learn to appreciate their opinion we should take advantage of the opportunities offered by such institutions as this (the American Museum of Nat-

ural History) or the National Museum at Washington. We shall find in these institutions a wealth of material, paleontological and anatomical, for various studies, and also come under the guidance and influence of the foremost scientists of the country. Thus we shall be led to realize the true value of orthodontia. For while we deal with the improvement of the individual, we are really also contributing something to the improvement of the race.

I also want to impress you with another fact, *i.e.* that the main idea of my endeavor to have us meet in this institution and obtain these men to deliver lectures to us was to show our members a path by which we may arrive at a better understanding of the various scientific angles from which our specialty may be approached.

In conclusion, I wish to express my gratitude to Professor Osborn, Dr. Gregory, and Mr. Sullivan for their co-operation and their willingness to aid us in every way to help in the advancement of science from our standpoint.

The President. I am sure Dr. Hellman has expressed sentiments which we all feel. We cannot say anything which in any way indicates the impression this lecture has given, because we have not had experience in the same direction, but it is probable that most of us have had experiences which have called for the same type of effort. I am not surprised that the gentlemen do not say more in discussion, but I am sure we all appreciate the efforts of Dr. Gregory.

Dr. Gregory (closing the discussion). First, referring to the more than kind remarks which Professor Osborn made, I want to call attention to the fact that I did not touch at all upon the question of the *origin* of the wedgelike tritubercular type of teeth. I simply stated that this is the primitive type that we find during the latter part of the Age of Reptiles, and that these other types were derived from it during the Age of Mammals.

While my conclusions, and those of some other investigators, were somewhat different from Professor Osborn's as to the probable steps leading up to the first

stage, no one who is familiar with the practical evidence at the present day would seriously challenge the fact that from this stage onward the story is perfectly clear. That is Professor Osborn's great contribution to the study of the history of the teeth—that he assembled so much evidence; and there is also so much evidence in this museum which is not yet published, in many families and orders of mammals, tending to show that the tritubercular type is the real starting-point of such diverse molars as, for example, a carnassial, flesh-cutting tooth on the one hand, and a crested herbivorous tooth on the other. I said nothing about the origin of the tritubercular type, because until we get more remains of mammals during the Age of Reptiles, we cannot say whether the inner or the outer cusp is the older, which is really the chief point at issue between the two different schools of paleontologists.

Secondly, as far as I can see, the correlation of upper and lower teeth is much closer and more rigid in types with an orthal jaw motion, as in some of the carnivora. That is, there is not so much opportunity for variations in the exact relations between the parts of the upper and lower teeth; every point in the lower must fit in one corresponding space or depression in the upper series; but where there is a side swing there is room for a great variety of patterns, and there is also considerable variation both in the precise placing of the cusps of the upper and lower teeth, so that possibly the orthodont relations between the cusps is much more exact in some individuals than in others.

In studying the orthodont relations of the teeth of Eocene lemurs I have found that when the lower teeth sweep across the upper there is more chance for certain parts to slide across each other; for example, in one animal a certain lower cusp (entoconid) articulates a little lower down on the internal cusp of the upper molar, and in another a little farther up. Therefore I venture to ask you, as specialists, whether the human type, with its comparatively flattened crown and milling jaw motion, may not have

wider range of possible orthodont relations than in such animals as have a rigid orthal motion, as in the carnivora?

The PRESIDENT. It is seldom that we have upon the same occasion two lectures of such great value as we have had this afternoon, and I shall be pleased to entertain a motion of thanks to Dr. Gregory and Mr. Sullivan.

Dr. HELLMAN made such a motion, and it was carried unanimously.

The meeting then adjourned until 8 P.M.

— EVENING SESSION.

The evening session was held at the Museum of Natural History, the president, Dr. Murlless, calling the members to order at 8.30 o'clock.

The PRESIDENT. The next order of business is a paper "On Healthy and Diseased Conditions of the Alveolar Processes of the Jaws," by Dr. A. HOPEWELL-SMITH, Philadelphia, Pa.

[This paper is printed in full at page 426 of the present issue of the *Cosmos*.]

DISCUSSION.

Dr. Wm. K. Gregory. I would like to ask Dr. Hopewell-Smith about a certain point shown in one of his slides. It showed a basal cingulum on the molar teeth of the hyæna. That is a structure of great interest to the paleontologist, because the cingulum is very characteristic of the teeth of the most ancient mammals, and it is very likely that the ancestors of many living groups once possessed strongly developed cingula in both the upper and the lower molars, and that later the cingulum became atrophied, and in man has nearly disappeared. In man Carabelli's cusp seems to represent the remains of the cingulum, as shown in primitive types of human molars and in the chimpanzee. I would like to ask Dr. Hopewell-Smith what his idea would be as to the function of the cingulum in the hyæna, and also as to its minute structure.

Mr. L. R. Sullivan. Dr. Hopewell-Smith's paper was highly instructive. I was especially interested in his remarks on the degeneration of the molar series in modern man, and the statement that the incisor teeth are usually the last to be lost. I am wondering whether or not Dr. Hopewell-Smith can throw any light on that condition of the molar teeth known as "taurodontism." This condition is characteristic of the Neanderthal and Heidelberg molars. The roots of the teeth are shorter and less distinct than in *Homo sapiens*. Should this character be regarded as a specialization or a retrogression?

Dr. Milo Hellman. What I am particularly interested in, and what I think should be of interest to most orthodontists, is the question of the effect of anemia and hyperemia upon the tissues involved in orthodontic operations. I think this question has a great bearing on the degree of response obtained during treatment. Dr. Hopewell-Smith has made it clear that under anemic conditions bone absorption is enhanced. It would therefore, account in many instances for the perverse conditions brought about in response to the mechanical stimulation by means of the orthodontic appliance. This is one point of value in the paper that has a direct bearing upon our work.

Another point is the question of hyperemia. I did not quite get the essayist's idea of its influence upon the bone changes occurring during treatment. I think, however, that it has an intensifying effect upon the calcification of the bone. If that is so, the bone would not be as responsive to pressure as normal bone.

A further statement of interest is the one Dr. Hopewell-Smith made with regard to the resorption of bone with age. If I understood him correctly, he said the absorption is not interstitial. I should like him to explain that. I have seen sections of long bones, as well as of jawbones, which show that with the increase of age the thickness and number of bone spicula in the spongy bone portions decrease: for instance, the head of the femur in a young person has a great

many more and stouter spicula than that of an old individual; in the young the spicula cover a larger area than in the old, but with the increase of age the number of spicula decreases. What is true of the long bones is also true of the cancellous portions in the jawbones. If this is so, would it not constitute interstitial resorption of bone?

With regard to the intensification of the bone portions situated between the roots of the molar teeth of anthropoid apes, I would like to ask whether the essayist has observed similar sections of the same species in young individuals, and whether the tissues are of different texture. For instance, I have in mind the orang. The orang dentition shows a considerable amount of wear at an early age. The wear of the teeth in the upper jaw, for instance, is at the expense of the lingual cusps of the premolars and molars. In proportion as this is manifested by the teeth the apical two-thirds of the buccal roots of the molars become denuded, and are visible through the external plate of the alveolar process.

I would therefore ask Dr. Hopewell-Smith to tell us if he has observed any such sections of the same species in the young before the projection of the roots occurs, and if the bone tissue situated between the molar roots is of a like texture in the young as observed in the adult animals.

It would seem that the dense bone tissue referred to by Dr. Hopewell-Smith is the buccal plate of the alveolar process after such change has taken place in the dentition of the ape.

Dr. H. C. Ferris. I want to thank Dr. Hopewell-Smith for his excellent presentation of the question. I want to ask a question or two in reference to pathological findings pertaining to our work. One is, whether he has noticed any differential pathological picture radiographically in osteomyelitis in other parts of the body than in this region of ours?

Another practical point is: We frequently have radiographic records made of cases that we are working upon, and find a very much thickened area in the region of the teeth under continuous

movement. Those pictures are often diagnosed as pathological, due to infection. At the completion of our work, that tissue seems to be rebuilt and gives a normal radiograph. If you would explain to us the histological process as compared with the pathological, I think it would be of great interest.

Dr. B. W. Weinberger. I desire to ask Dr. Hopewell-Smith his opinion concerning the absorption of the roots of teeth. This was not quite clear in his paper just read. He mentioned the non-eruption of laterals, but failed to state the cause of absorption of deciduous molars where there were no premolars to take their place. Is it the vitality of the bone structure, or is there some other explanation as to the cause of absorption?

Dr. Frank Gough. Along the same line Dr. Weinberger has spoken of, I would like to find state that in my observation of radiographs, there have been many cases in which the roots of the deciduous teeth would be absorbed, and in others they would not. Even in the same mouth, an upper second deciduous molar on the right side, which was not succeeded by a permanent tooth, had fully formed roots and no absorption whatever, while on the opposite side the roots were entirely absorbed, and there was no bony attachment whatever.

Dr. B. W. Weinberger. In line with my first question and extending the question asked by Dr. Gough, we find a great many cases where either the anterior or posterior roots of a deciduous molar will absorb and the other roots of the same tooth will remain normal, thus preventing the premolar from erupting. Has the essayist any explanation to offer for these phenomena?

Dr. Hopewell-Smith (closing the discussion). In regard to the question of Dr. Gregory, I think I might say that the structure of the cingulum is probably very much like an anatomical condition found in the deciduous teeth. The deciduous molars, for example, possess constricted necks below the enamel. There is a special bending there of the dentinal tubes, and I believe, although I have not examined particularly the cingulum of the hyæna, that we should

find the same condition there. No doubt the presence in a deciduous molar of a rather prominent cervical edge of enamel acts as a preventive of injury to the succeeding tooth. In relation to the second premolar in man, probably the internal cusp may be an elevation of the end of the cingulum. That is an interesting point, but not thoroughly determined.

A question was asked as to the late retention of the mandibular incisors in a certain picture I showed on the screen. I have not examined the jaw microscopically, but I believe the alveolar process is retained, because of its resemblance to compact bone elsewhere. There would seem to be a condition of the bone here which has a different structure from other portions of the alveolar process.

I should regard bone absorption as a retrogressive step. I think it must be considered so, because I am of the opinion that the teeth themselves are degenerate as well as their sockets. Man is anatomically a degenerate being.

Dr. Hellman asked about hyperemia. There is not very much known about its effects on the subject under discussion, because there are not sufficient data. We can only surmise that anemia favors absorption, and hyperemia, I think I said, favors a consolidation of the bone. If it remains a hyperemia, well and good; but if it goes on to an acute inflammation, an absorption of the alveolar processes occurs at the same time. It is not quite clear which is better—anemia or hyperemia; both are bad.

There is simply a change in which the medullary spaces become enlarged, and the bone becomes osteoporous—thinner and fragile—and breaks easily. Osteoporosis is frequently found in old people who have been bedridden for years, and even the moving of the person from one bed to another may cause the fracture of, say, the femur because of that condition. Patients in hospitals frequently have fractures of the femur from just that cause.

As far as I know, the sockets are very closely allied in man and the anthropoid apes. I have not studied that point very extensively.

Dr. Ferris. At the present time, the study of pathological conditions in mouths being treated by the general practitioner is being severely criticized by the medical fraternity at large; they are trying to put the burden of infection upon the dentist. The medical man is also closely observing the orthodontist, and once in a while, when examining mouths where there are a dozen pictures taken, for instance, of one jaw, he finds conditions in the region of our work which appear to be a thickening of the area, and immediately marks that as a pathological area. Then he immediately asks us for an explanation. In several instances I have claimed that the condition was due to a normal—or rather a traumatic—disturbance due to the pressure of my apparatus. The slow, continuous pressure I believe has set up a minute multiple fracture in all the lacunæ of the bone, and I think that was the cause for the thickening shown in the picture. After the case has been retained and functions restored for six or eight months, other pictures have been taken, and they show the region cleared up. I would like to know whether I was right or wrong in my conclusion.

Dr. Hopewell-Smith. I think with a slow movement you are causing a hyperemic condition of the parts. You also get probably some hyperplasia of the parts. You do not mean rarification?

Dr. Ferris. No; where absorption has taken place, of course there is a rarefied area.

Dr. Hopewell-Smith. My opinion is that it is exceedingly difficult to tell just what is going on there. You may see an area where the rays pass through more clearly, and that may be an alveolar abscess, a dental cyst, or a sarcoma. I had a case of a man with a fractured maxilla, which was properly treated. An X-ray was taken. Six weeks after, when union was established, another X-ray photograph was taken, and showed no formation of callus, in spite of the fact that it existed. We have not yet learned to always interpret X-ray photographs correctly.

Dr. Ferris. If pressure is applied to a root, is a hyperemic condition stimu-

lated, and would that prevent the ray from passing through?

Dr. Hopewell-Smith. Yes; I think that would be the case. If there is rapid movement, you would get a fracture.

Dr. Ferris. You spoke of the local pathological condition, such as pyorrhea; but you made no mention of the constitutional condition.

Dr. Hopewell-Smith. Except by malnutrition and chronic wasting by disease. It leads to anemia.

Dr. Ferris. Is there no differential picture shown?

Dr. Hopewell-Smith. I do not think so.

Dr. Ferris. In cases of arrested development, or sclerosis, we determine by the X-ray whether the process was underdeveloped, or whether it was natural.

Dr. Hopewell-Smith. I do not think I can enlighten you further on that.

In regard to the question about absorption, someone asked why the tooth should remain longer on one side than on the other. I think it depends largely on the vitality of the tooth. If it is a "dead" tooth, I do not think it absorbs as readily as a vital tooth, and the fact of the tooth being vital or devitalized I think would account for the absorption of one root and not another. At times part of the pulp may die, and part of it remain vital; and when absorption is going on, the part containing the vital tissue would absorb much more readily than the other part which was not vital.

I am sorry I have not been able to clear up all the questions, but I thank you very much for your kind attention.

Dr. HELLMAN moved a vote of thanks to Dr. Hopewell-Smith for his very excellent paper. The motion was unanimously carried.

Dr. HELLMAN also moved that the secretary write a letter of thanks to the president of the Museum for the very courteous treatment accorded the society. The motion was carried.

Dr. LAWRENCE BAKER of Boston then showed a number of lantern slides of skulls illustrating the harmonious relation between arch form and head form, after which the society adjourned.

EDITORIAL DEPARTMENT

Dentistry in the New Era.

"THE rapid strides which dentistry is and has been making along the highway of professional progress" is a statement which, in one form or another, has become trite from frequent repetition. This progressive development manifests itself in a variety of ways, and is estimated from a number of different angles depending upon the point of view of the observer.

In past decades the changes of eloquence were rung in terms of wonder and admiration on the ingenuity and resourcefulness displayed in the development of the technique and armamentarium of the up-to-date dental operator, his mechanical skill, his craftsmanship, his manipulative ability. We hear less of these things today; they have become matters of course and are taken for granted. The latter-day development has taken a new direction, or, more accurately, a more intensive growth along an old and one-time subsidiary course, namely, its function as an important department of the healing art. No one today who is alive to the

meaning and significance of the modern trend of thought in health matters thinks of dentistry in any other terms than as a factor of health. The dentist recognizes for himself and for his profession that his service is primarily directed toward the cure and prevention of disease. The lay public seeks dental service with the same object. Step by step the relations of dental and oral disorders to general health conditions are being defined by scientific research and by clinical observation and experience, so that the earlier and indefinite ideas concerning the relations of sound teeth and a clean mouth to a healthy body are being rapidly confirmed by a mass of data which make clear just what and how important these interrelationships of oral conditions and bodily health and disease really are.

The real progress of dentistry, then, is that phase of its development which has brought about a recognition of its normal relationships with the science and art of healing. It is not within the purpose of this writing to direct attention to the various factors that have wrought out the present dominating motive in dental activity, but rather to call attention to some of the results which seem reasonably certain to flow therefrom.

The oral hygiene propaganda, viewed broadly, has served to educate the public in the belief that a long category of diseases have their hitherto unsuspected origin in the infected mouth—a view amply confirmed by the studies and observations of physicians and dentists alike, and in many cases verified by scientific research. Besides the disorders arising from an unclean mouth are the infections dependent upon apical root diseases, and further, the increasing number of reflex nervous disturbances originating from physical irritation of the peripheral nerve filaments ending in and about crowded or impacted teeth—the choreas, dementia, epilepsy, neuralgia, etc., of malocclusion. The list, already a long one, is also an increasing one as investigation continues to bring to light fresh evidence of the dental origin of many of these heretofore obscure conditions.

In view of the rapidly increasing evidence of the important rôle which the teeth and their disorders play in relation to general health—and this fact taken in connection with systematic and wide dissemination of information concerning the general health relations through oral hygiene propaganda, through medical channels, and lately through such agencies as the Preparedness League and the

Dental Surgeons Corps of the army and navy—we must expect and prepare for a largely increased demand for dental service on behalf of the major part of our population who are at present inadequately served dentally or are without dental service altogether.

To minister to the needs of our national population of one hundred millions of people we have in round numbers fifty thousand dentists, or one dentist to two thousand of population, which is, roughly speaking, one-fourth of the number of dentists required.

When from time to time these figures have been under discussion, the objection has been urged that "Only a minor proportion of the population seek the services of the dentist"; and again, it has been as frequently said that "Dentistry is a luxury which only a relatively few can afford." Taken together, it is not at all unlikely that in a considerable degree the latter may stand to the former objection in the relation of cause and effect. At any rate, it is evident that the demand for dental service is a growing one, and one which seems destined to grow in increasing ratio. It has already reached the point where the question of bringing dental service within reach of the masses of people of limited means, the small wage-earner whose income barely provides subsistence and the cost of whose health maintenance is now borne by the state or by charitable institutions, is a problem pressing for adequate practical solution.

The experience gained in the conduct of dental service in municipal dispensaries and eleemosynary institutions, and above all, the experience now being gained in the dental care of those engaged in military service in the world war, will constitute an invaluable demonstration of the fact that dentistry is not primarily a luxury but a necessity; that dental service, the major objective of which is to eliminate dental and oral disease, is a different thing from the elaborate and expensive dentistry which involves the esthetic and adornment features demanded by the luxurious and well-to-do.

There is possible a dental service which, by eliminating oral disease, is a conservator of health—a service which, because it is inexpensive, should be brought within the reach of all. It has been amply demonstrated that it requires decidedly more of the taxpayers' money to maintain a retarded child an extra term in school than it does to pay for putting his mouth in a healthy condition, and when it is considered that at least a third of the re-

tarded cases are due to bad mouth conditions the economics of the case are alone ample reason for compulsory dental attention among school children.

In view of the prospective largely increased demand for dental service in the near future, steps should be actively taken to induce a larger number of qualified young men and young women to engage in dentistry as a profession. To adequately care for the dental needs of the whole population, not less than two hundred thousand dental operators would be required. The opportunities and advantages of dentistry should be brought to the attention of those who are considering their life-work, and this can best be done by the practitioner in daily contact with his *clientèle*.

The avenues of entrance into the dental profession should be made less difficult, not by any compromise in the matter of educational standards, but by the adoption of educational requirements logically adapted to securing matriculants having the best kind of training for entrance upon the professional course.

The heterogeneous character of our state laws regulating the practice of dentistry needs fundamental revision so that general reciprocity in the matter of interchange of licensure among all of the states may become an accomplished fact.

But the most important need of all is a general appreciation by the whole dental profession of the greatly enlarged field for dental service which the immediate future offers. Such an appreciation should result in an aggressive campaign having for its main object the extension of adequate dental service for the whole population, the reorganization of those features of our educational and dental legislative methods that now operate as obstacles to such general dental service, and most important of all, it should bring about the elimination of the spirit of selfish trade-unionism wherever it exists, the spirit that would artificially limit the number of practitioners in a given locality to restrict competition. The world is being remade, new social conditions are being created, and when the period of reconstruction and reorganization succeeds the present agony of conflict and slaughter the signs of the times all point to the establishment of new ideals of altruism as the dominant feature of the world's social organization. Good judgment and wisdom dictate that dentistry should even now begin to shape its activities so that they shall be in harmony with the new order.

BIBLIOGRAPHICAL

LORD LISTER. By SIR RICKMAN P. GODLEE, Bart., F.R.C.S. London, Eng.: Macmillan & Co., Lt. 1917.

With a modesty quite uncalled-for, suggesting himself in his preface as one of the band of "amateur authors," Sir Rickman Godlee has placed a wide circle of readers under contribution of thanks and gratitude. Lister was no ordinary man, and we are fortunate in having the great savant's life-work brought within the intelligence of ordinary mortals. Himself a student from first to last, the story of his life is a book that should be in the hands of every student, irrespective of age, for in it there is not only the record of infinitely patient research, resulting in the highest good to his fellowmen, but there are glimpses of an individuality of the purest integrity, coupled with a modesty and simplicity that united to form a character almost if not quite unique. The inner Lister is not completely revealed to us, though of such an actuality there is no manner of doubt—and, after all, only the high-priest has the right to enter into the holy of holies of a man's inmost soul, even though the veil of the temple has long since been torn in shreds. To his nearest and dearest, alone, did Lister in his lifetime reveal what was deepest in him, and his feelings in this matter have been admirably respected.

Lord Lister died in 1912, his life culminated yet his work never done—as was shown by notes and jottings that he evidently intended to amplify; and no

doubt, in view of these, some heart-searchings must have taken place as to the greater propriety of quickly giving his history, if possible, a wider field, or of delaying publication until a clearer estimate of the full value of his life-work could be arrived at through the course of years. The opinion is respectfully ventured that the right time has been selected, and that prolonged delay in publication would have been a misfortune. Whether another biography may appear at a later date is a matter that does not concern us, but it cannot be forgotten that there are many today who remember the distinctive yet quiet personality, and are enabled through these pages to recall the living man.

It is not every biographer who can allow his subject to tell his own story, but Lister's environment and transparent honesty of heart and purpose make this a happy possibility. For the most part we are brought in close association with the master and the celebrated men of his day, and are allowed, as it were, to hear them speak, and pages full of professional cares and triumphs and family associations are little more than edited by a hand at once sympathetic and judicious. That this fascinating correspondence should appear in type so small as to be an irritation to possibly a large number of readers is a matter concerning the publisher, who has perhaps in this, as in other ways, not quite done himself justice.

It is curious to read in contemporary medical literature not only the hostility

that the enunciation of the principles of the practice of the antiseptic method produced, but the vituperation that was poured upon Lister. There have always been—there are now—men too ignorant to know and too stupid to learn, and when antiseptic surgery (not carbolic acid treatment) was born in Glasgow in the “sixties,” the vials of envy, malice, and all uncharitableness were uncorked with a volubility which was only equalled by its vehemence. They meant well, those men (at least we hope so), but the irony of fate remains that their place in remembrance, not of fame, is their hostility to Lister and his system of treatment.

If the biographer has been fortunate in his subject, Lister has met a Boswell with whom knowledge and affection go hand in hand, and yet Sir Rickman Godlee, in spite of this, suffers at the hands of his “reader,” to whom he generously ascribes his thanks. It will startle the Glasgow student to learn that the site of the Western Infirmary was separated from that of the University only by the river Kelvin, the fact being that both

buildings are on the same side of the river. While this is a trifle, historical fact is boldly set at defiance by the statement on page 33 that Sir James Y. Simpson was the “discoverer” of chloroform. Like Lister, Simpson is one of the glories of the Scottish (not Scotch) school, and while modesty was perhaps not one of his outstanding traits, he would have, it is to be hoped, stood in uncomfortable shoes on hearing himself described as the “discoverer” of chloroform, a reagent whose anesthetic properties he had the honor to introduce to a suffering world.

What has been done by the author to enshrine the spirit of Lister is in the main admirable; the same, however, can hardly be said of the shrine. In addition to the smallness of the print in the correspondence, the paper on which the impression of this great master-mind is imprinted is poor, and the student has to put himself back into the Victorian period in having to cut the volume before its treasures can be enjoyed.

The Significance of the Tubercle of Carabelli. BY E. JEANSELME.

The above titles represent the major part of a discussion which has grown around a statement of Sabouraud (see DENTAL COSMOS, July 1917, p. 759; Oct. 1917, p. 1043) that an accessory cusp on the lingual surface of the maxillary first molars is in the highest degree pathognomonic of congenital syphilis.

In article 1 there were examined 60 children, who were known to be afflicted with congenital syphilis, and 1400 patients, rachitic or tubercular, children or adults. The histories of these cases were unusually complete. The work was thoroughly done, with radiographic and serologic control.

The results are: (1) Among the congenital syphilitics Hutchinson's teeth were found 4

times; the authors observed but once the maxillary molars carrying on the anterior part of their lingual face the fifth cusp; the Wassermann in this case was strongly positive. (2) Among the other patients, in whom it was impossible to discover any recognized syphilitic taint, this fifth cusp was found clearly and unmistakably 19 times. These clinical data, verified by the laboratory, show that this new "sign" of congenital syphilis does not in reality possess any such value. This fifth cusp does not appear to have, from the point of view of syphilis, the interest attributed to it by Sabouraud.

Article 2 describes in detail a case which to the authors confirms the hypothesis of Sabouraud. It is a case of unmistakable congenital syphilis, and the dentition of the patient presents this fifth cusp. This is merely an example of coincidence, and is without value in proving the validity of Sabouraud's "sign."

Article 3 is the most extensive of the ones collected, and at the same time pre-eminently sane and judicial. It has been admirably summed up in the *Journal of the American Medical Society* as follows: Galippe devotes 41 pages to demonstrate that physicians have paid too little heed to the work of dentists, and hence when they find peculiar dental malformations in their syphilitic patients they ascribe them to syphilis. If they had wider experience with teeth they would find that to date there is no dental anomaly of shape, size, site, or structure which belongs exclusively to congenital syphilis and cannot be found with other congenital taints.

Article 4 gives the following argument: Seven tuberculous patients were found who presented clearly the fifth cusp. None of these presented in their personal or hereditary antecedents anything which could be suggestive of congenital syphilis. The most careful examination of each of them failed to reveal

a single acknowledged stigma. Five of the seven gave negative Wassermanns, while the other two gave positive. Both of these were affected with acquired syphilis. Mantoux is convinced that the fifth cusp is not a sign of congenital syphilis.

Article 5 consists of two brief notes. The first one likewise essentially appeared in *Paris Médical*, November 24, 1917. It is a consideration of the coincidences of the fifth cusp with various other oral anomalies. Railliet finds a to him impressive coincidence between the frequency of the fifth cusp and leucoplakia (out of 100 patients with the fifth cusp, 35 showed leucoplakia). The author decides that without further examination (and he is cognizant of the work of Mozer and Chanut, Mantoux, and Galippe), one cannot contradict the correctness of Sabouraud's assertion. In this he appears to forget that the novelty of the assertion places the burden of proof upon its advocates. The second note was upon a study whose material was furnished by 65 children, between three and eighteen years—18 of the 65 showing the fifth cusp. Of these 9 were without permanent teeth, and showed the fifth cusp on the maxillary second premolars. In those cases where Railliet was able to see the environment, and particularly the brothers and sisters of the little patients, it was rare that their fifth cusp did not find its justification in the family pathology. He believes that the fifth cusp represents a dystrophy, oftentimes sequent to a syphilitic ancestry.

Article 6 represents an American echo of this controversy. In a former paper (*DENTAL COSMOS*, Oct. 1917, p. 1037) Roberts inculpated widely-spaced incisors as a frequent anomaly most suggestive of congenital syphilis. He has become aware of Sabouraud's views, and apparently agrees with them perfectly. To the molar with the fifth cusp he assigns the very awkward and decidedly non-descriptive term "humpy molar." This is present in a large percentage of subjects with proved congenital syphilis. Moreover, it is seen on the permanent second molars, and in Roberts' series it appeared on the deciduous molars.

Article 7 is the most interesting of this group of papers. Jeanselme approaches the subject from the broad viewpoint of history and biology. Within this report is included an earlier one in the *Bulletin de l'Académie de Médecine*,

Paris, 1918. The fifth cusp is clearly represented in from 17 to 20 per cent. of the population. It is represented in a less sharply defined form upon the molars of about 40 to 45 per cent. of subjects examined. It shows an hereditary tendency by apparently running in families. Among idiots, epileptics, etc., or deaf-mutes, it can be associated with other aberrations of odontogenesis, but this in Jeanselme's opinion is a pure coincidence. It was present at all times in paleolithic and neolithic man.

Twenty-three men, in whom there could be found no other "sign" of congenital syphilis than this fifth cusp, well developed, gave invariably negative Wassermanns. The author refers to the work of Collin and Souffland, who in 10 abnormal children presenting this fifth cusp found only one positive Wassermann. A second series worked over by Jeanselme may be tabulated as follows: There were 59 patients in all, of whom 21 (35 per cent.) lacked the fifth cusp, 29 (50 per cent.) had fifth cusps in a rudimentary state, and 9 (15 per cent.) had a well-developed fifth cusp. In the first group there was only one positive Wassermann; in the second group there were 5 positive Wassermanns, and in the third group not a single positive Wassermann. These data do not favor the view that the fifth cusp is an infallible indicator of a syphilitic taint.

The evil significance attached to the fifth cusp does not accord with either view as to the history of syphilis. It is as frequent in European dentures before the great epidemic recrudescence of this disease at the end of the fifteenth century, as it is now; and it is rare in pre-Columbian American skulls.

In conclusion, syphilis is definitely removed from having any influence in the production of this cusp. It is difficult to sustain the view that this cusp is the vestige of an atavistic form. Jeanselme is inclined to accept the view that it represents the remnant of the anthropoid cingulum. From this phylogenetic interpretation may be deduced the practical conclusion that the fifth cusp, the tubercle of Carabelli, is not a sign of congenital syphilis.

Considering the scanty support adduced by the adherents to Sabouraud's thesis for their views, one cannot help wondering at the attention which has been given to this subject.

All that has ever been proved by the advocates of the sinister interpretation of the fifth cusp is that this and congenital syphilis may occur in the same individual. They have even been unable to show that this coincidence is of a frequency in any way peculiar. The admirable and critical work of Mozer and Chenet, Galippe, Mantoux, and Jeanselme has incisively demonstrated that there is absolutely no causal connection between the syphilitic virus and the fifth cusp.

[*New York Medical Journal*, February 9, 1918.]

Kidney Infection as a Result of Pyorrhea.

By FRANK S. CROCKETT.

At weekly intervals the patient had temperature elevations reaching 104° F., preceded by chill. These would last one or two days, followed by several days' remission, with only a fraction of a degree rise in temperature. The urine was cloudy, and cloudy urine could be seen coming from the left ureter on cystoscopy. Immediately after removal of the kidney (which had 2 pelves and 2 ureters) the temperature fell to 99° F. and a fraction, fluctuating to normal. Some three weeks after this operation, soreness over the right kidney developed, and the temperature shot up to 104° F. The urine became loaded with pus. The teeth of the patient, who for a period of at least a year had been afflicted with pyorrhea alveolaris of moderate severity, were the most patent source of possible infection. They were promptly removed. There was a prompt remission of the fever and pain over the remaining kidney, and the disappearance of pus in the urine. The patient made an uneventful recovery.

[*British Medical Journal*, London, January 19, 1918.]

A Serological Investigation of Vincent's Angina. By F. E. TAYLOR AND W. H. MC-KINSTRY.

Several contributors, scattered through the literature, maintain that in uncomplicated cases of Vincent's angina the Wassermann reaction is often found to be positive. This opinion is quite contrary to that of the authors, which is based on several hundred cases of sore-throat at the Queen Alexandra Military Hospital. According to their findings the Wassermann reaction is positive in syph-

ilitic affections of the pharynx, and negative in all others with the exception of the angina of scarlet fever.

The authors had occasion to examine bacteriologically more than three hundred cases of fuso-spirillary infection, and about one-half of this number were typical cases of Vincent's angina verified by bacteriological findings. From this number there were taken at random fifty-five cases for the Wassermann. In all these cases, with but two exceptions, no fixation of complement could be observed, i.e. a negative Wassermann. The two positive cases admitted a syphilitic infection. The remaining fifty-three cases were quite negative. The positive reaction in the two cases admits of a ready explanation, and was not due to the fuso-spirillary infection of Vincent. In both cases the condition was one of Vincent's angina in a subject of latent syphilis.

As a result of this investigation and a careful and critical consideration of cases recorded in the literature, the authors have come to the conclusion that the prevailing belief in the occurrence of a positive Wassermann in Vincent's angina has no foundation in fact, and that the two conditions can be differentiated with absolute certainty by the application of bacteriological and serological methods; and that when the complement-fixation test of Wassermann is positive in cases of Vincent's angina, a double infection exists, either as a coincident syphilitic and Vincent's infection or as the occurrence of Vincent's angina in the subject of latent syphilis.

[*American Journal of the Medical Sciences*, Philadelphia, February 1918.]

The Pathogenesis of Infantile Scurvy: An Hypothesis. By H. J. GERSTENBERGER.

There are two principal lines of thought along which attempts have been made to explain the etiology of this disorder—(1) that it was the result of an infection or toxemia, and (2) that it was due to the destruction of some substance in the diet whose presence is necessary to prevent the development of the characteristic symptoms, i.e. absence or inaction of "vitamines," "accessory growth factors," or one of the known food constituents. The views of the present article are more closely allied to the latter concept.

Gerstenberger here offers an hypothesis, and

he makes it clear that he is doing nothing more. The hypothesis is divided into four parts: (1) All the symptoms of scurvy as we know them today may be explained on the common basis of a primary or secondary interference with one or more of the normal functions of calcium, alone or in conjunction with its physiological anion. This condition may be denominated "a partial defunctioning of calcium and its physiological anion." This first part of the hypothesis, alone, is considered to be based sufficiently on experimental and clinical data to permit its exit from the domain of pure hypothesis. (2) In infantile scurvy this defunctioning is caused by a substance produced through a break in the metabolism of carbohydrates, whatever their original source may be. (3) The break in carbohydrate metabolism occurs as a result of the absence or inactivity or relative insufficiency or inadequacy of some physico-chemical substance or "vitamine" essential to the establishment and performance of normal carbohydrate metabolism. This view has already been advanced by other investigators. (4) The defunctioning substance produced as a result of the break in the metabolism of carbohydrates due to a disproportionment between the carbohydrate supply on the one hand and the "vitamine" supply on the other possibly is oxalic acid, or some other agent that has a similarly strong affinity for calcium and that after combining with calcium is soluble with similarly great difficulty.

The second and third parts of the hypothesis are considered to have as a basis experimental and clinical data that are distinctly suggestive, while the fourth is still purely hypothetical, although on its assumption it is possible to explain satisfactorily some of the clinical phenomena of scurvy that hitherto have not even had a hypothetical explanation.

The interference with normal calcium metabolism is indicated by the increased permeability of the vessel walls and the osseous lesions in scurvy. There is a close connection between the severity of the bloodvessel lesions on the one hand and of their proximity to the bones on the other. "This is most beautifully demonstrated by the lesions occurring in the gums only when the teeth are erupting or have erupted; in other words,

at a time when the alveolar periosteum is very active, and when the gums have become firmly attached at the neck of the tooth to the tooth and to the periosteum."

[*Journal of Laboratory and Clinical Medicine*, St. Louis, December 1917.]

An Experimental Study of Root-filled Teeth: Preliminary Report. BY M. B. COHEN.

That root-canal filling in average hands does not eradicate periapical infection is shown by the following study of six cases of polyarthritis:

Sixty-two cultures were made from "locked areas" beyond the apices of eighteen teeth which had been filled from six months to twenty years previously. Growth was obtained without exception from each of the sixty-two cultures on some one of the media used. The organisms usually isolated were those found normally in the mouth. The streptococcus viridans was the predominating one: it occurred in sixty cultures. The staphylococcus family was represented in sixteen, always in association with the streptococcus, while the colon bacillus was isolated in pure culture once. One culture yielded *B. acidophilus*.

[*Medical Record*, New York, January 26, 1918.]

Streptococcus Oral Sepsis: Complement-Fixation Test and Value of Routine Blood Examinations. BY N. B. POTTER, A. MCNEIL, AND S. BRADBURY.

This study represents a much-needed step in the right direction. For a long time we have been morally certain that oral sepsis was an important factor in more general disturbances, but the careful analyses of this relationship have been all too few. The present report is not only founded upon data afforded by the most painstaking and strictest procedures of laboratory science, but also—and this fact lends them peculiar value—controlled by long-continued clinical observation.

The first part of this paper deals with the particular problem, Is it possible to demonstrate the presence of immune substances (called forth in response to the irritation of streptococci of oral foci) in the blood of persons suffering from various types of systemic disturbance which are suspected of being men-

tastatic from oral foci? The principle of this interrogation is quite analogous to that underlying the well-known and reliable test for syphilis.

The technique used in making these tests was identical with that of the classical Wassermann test, excepting that an antigen prepared from several varieties of streptococci was used. The strains of streptococci from which the antigen was prepared were obtained from clinical cases showing widely varying conditions of streptococcal infection. Complement-fixation tests were carried out on about eighty patients, as indicated clinically.

Twenty-one of these cases have been very carefully followed up for two years or more, and have largely recovered or very decidedly improved, due, the authors believe, to the elimination of a definite focus of chronic infection, usually in the teeth or tonsils. The authors are convinced of the preponderating importance in etiology and treatment of these minor streptococcal infections in many serious conditions or chronic invalidism.

Even with an imperfect antigen, the results of a complement-fixation test for streptococci in the oral sepsis complicating or causing many forms of chronic invalidism support in general the clinical evidence of the etiological, prophylactic, and therapeutic importance of this organism, and emphasize the desirability of further attempts along this line to assist diagnosis.

The second part of this paper reports the results of routine blood examinations in pertinent cases. Of fifty-five carefully studied cases of oral sepsis, twenty-five were selected for analysis. The others were excluded because of some important pathological condition other than oral sepsis. The only suggestive feature exhibited by a routine examination of the blood is a high normal lymphocyte percentage, which, however, is certainly no more striking than in any collections of patients who consult a physician for some minor ailment.

Paget's Disease of the Bone. BY ROBERT ABBE.

The author had two purposes in making this report: (1) To call attention to the admirable repair of such diseased bones when

surgical operation is called for, and (2) to direct attention to its not infrequent occurrence in the jaw-bones, in order that it may not come unrecognized under the notice of dentists.

The essential condition of this disease is one of very chronic osteitis, productive of spongy overgrowth, with absorption of the compact structures in the long bones, and occasional development of cysts lined with epithelium, sometimes filled by fluid or granulation tissue.

In fourteen private cases four showed involvement of the jaws. In two of these, extensive surgical operation was required, and most excellent results were obtained.

Two such cases are described.

Case 1. Female, whose lower jaw had been treated for a cyst on several occasions for twenty-two years. A roentgenogram showed a very thick skull, typical of Paget's disease. Abbe extensively removed the outer plate, and all the cancellous and cystic structure of the forward half of one side of the lower jaw, leaving the inner compact structure.

Case 2. Male, for many years a victim of an enormous and repulsive overgrowth of the alveolar roof of the mouth. Roentgenoscopy showed the large characteristic overgrowth of the calvarium. A horizontal block of bone, more than one inch thick, was removed.

Both of these cases illustrate the very slow development of the disease.

[*British Dental Journal*, December 15, 1917.]

Bismuth Poisoning as Affecting the Oral Cavity. BY FRED. J. BLIGHT.

A somewhat analogous case is Freilich's—see the DENTAL COSMOS, 1917, p. 466. Bismuth paste (probably bismuth subnitrate, iodoform, and paraffin liquid) had been used in treatment of a comminuted fracture of the left forearm. Within a week the gums of the patient became painful. About three weeks later a bright blue line extending around the gingival margin of both maxillary and mandibular teeth was discovered. On examination the mouth showed a condition of ulcerative stomatitis. The teeth were slightly loose; some recession of the gums had occurred. The blue discoloration, which was found on both palatal and buccal surfaces

of the gingivæ, was entirely absent in places where teeth had been lost.

Before the wound the patient had been a fairly robust man, aged thirty-nine, with a clean, healthy mouth, but evidently with an idiosyncrasy to bismuth poisoning.

Removal of the bismuth dressing resulted in recovery.

[*Bulletin de l'Académie de Médecine*, Paris, 1917, No. 43.]

Senility of the Dental Tissues Among Soldiers. BY J. C. DEMARQUETTE.

Senility is accompanied by a mineralization, more and more accentuated. It is externally manifested by a modification of the color of the tooth, which becomes more and more opaque, and at the same time becomes yellow or bluish. Another very important effect of senility is seen in the course of dental extractions, where the elasticity of the osseous

tissues of the jaws is lost. This change is to be inferred from a much heightened incidence of fractures of the alveolar borders during extractions. A third effect of this senility is that the roots and the teeth, in general, although much harder, are also much more brittle.

The author has noticed a comparable senility of dental tissues among those who have dwelt in the tropics.

These symptoms of senility are very manifest in the army. The men of the young classes ('11, '12, '13, '14), who have been at the front three years, have dental and osseous tissues in the same state as those of men from thirty to forty years of age, in normal times. The author suggests that this senility may be attributed to fatigues, prolonged exposure to the rigors of the weather, rations too rich in nitrogen and alcohol and too poor in fresh vegetables, and perhaps to the action of neurotoxins produced by violent emotions.

PERISCOPE

Zinc Dies with Zinc Counters.—I should like again to repeat my conviction of the efficiency of zinc counterdies. They can be quickly poured on to very hot zinc dies without any coating, provided that the molten zinc is just beginning to crystallize, and no adhesion will take place. Having used no lead or tin counters for many years, I have no hesitation in again recommending this quick and efficient method to my colleagues.—H. J. MORRIS, *British Dental Journal*.

To Obtain Smooth Castings.—Exercences on inlays are a common trouble, but I have found that by casting with a rapidly falling temperature a smooth skin is obtained, provided they are carefully invested. I melt and boil the gold with a gas and oxygen or gas and nitrous oxid flame, and flux it with borax and nitrate of potash. It then has a creamy color, and moves rapidly under the intense heat. Now the flame is withdrawn and movement ceases, and after waiting a few seconds the casting is made. I have invariably by this method obtained a smooth skin for my inlays.—H. J. MORRIS, *British Dental Journal*.

Keeping Matrix Bands.—A convenient method in which to keep matrix bands after receiving them from the dental dealer is to remove them from the original package, sterilize, and put them in a bottle of oil of eucalyptol, thymol, and menthol; then cut a groove in the side of the cork, and drain off the surplus, and they will be sterile and ready for instant use. Replace a solid cork when through draining. Having them in a bottle you can see what you want.—Y. E. WHITMORE, *Dental Review*.

Apothesine.—Apothesine is similar in its behavior and in its action to novocain. It is a little quicker, perhaps, in its action, and gives as perfect anesthesia as novocain. This drug can be bought in tablets of different strengths, and can be used with adrenalin or without it. It can be dissolved either in Ringer's solution or in normal salt solution, and if necessary the desired amount of adrenalin may be added at the time the solution is made. This will give us just as good, if not better, results than we have obtained in the past from novocain.—LOUIS SCHULTZ, *Dental Review*.

Full Upper Dentures on a Gold Base.—

In making these it is not necessary or even desirable to extend the metal far over the highest part of the ridge, because a vulcanite rim will better exclude the air and promote the necessary adhesion.

The real strength of these dentures being in the vulcanite mounting, a very thin gold plate can be used, say No. 6 B. M. gage, and this can be easily swaged on one zinc die, having a zinc counter. So we secure ample strength together with a minimum of weight, gold, and thickness, and the thinner the base the easier it is for the patient to obtain a good adhesion, and the more comfortable the denture.

All upper dentures, especially full cases, should have their posterior edges turned up by means of a groove in the model. This gives a tighter fit, and greatly helps the patient to retain the piece in place.—H. J. MORRIS, *British Dental Journal*.

Chlorcosane Apparently the Ideal Solvent for Dichloramine-T.—

Chlorcosane is a straw-colored, odorless, tasteless liquid, made by chlorinating hard paraffin wax, by a process enabling it to take up from 45 to 55 per cent. of pure chlorin. Being in itself non-irritant and making a very stable solution, it seems to be the ideal solvent for dichloramine-T. To prepare a five per cent. solution ready for use, all that is necessary is to dissolve 50 grains of dichloramine-T in two ounces of the chlorcosane. In preparing the solution the antiseptic dissolves quite slowly in this oil, but this difficulty is easily overcome if about one-fourth of the oil is taken and warmed to about 80° C. (156° F.), before adding the dichloramine-T. In this warm oil the dichloramine-T dissolves readily with a little stirring or agitation. When this solution has been made, add the remaining three-fourths of the chlorcosane. If the solution is not reasonably clear, filter it through a fluted filter paper.—*Helpful Hints*.

Amalgam Fillings.—Amalgam is the most used and the most abused tooth-filling material. The practice of merely cleaning out a cavity and inserting a large pellet of amalgam is too common, and must be condemned. Amalgam fillings for proper insertion require as much care and nearly as much time as gold fillings, are often their equal for service and saving the tooth, and when properly inserted and finished are fillings of beauty. One is constantly seeing amalgam fillings inserted in teeth in which there has been poor cavity

preparation and no attempt at anatomical restoration of the tooth, with poorly mixed alloy and without the use of a matrix.

The teeth in which amalgam should be used are especially the bicuspids and molars; these teeth are sometimes so badly decayed and broken down that amalgam is the only material with which to fill and restore them to usefulness; sometimes it is the only material that can be used to save a tooth from being extracted.—C. H. WOOLGAR, *Dental Summary*.

Dental Treatment for Mothers.—

Dr. J. Francis Taylor, the medical officer of health for Leyton, Eng., reports that the infant welfare and antenatal clinics are making rapid strides in popularity. Attendances and results are most satisfactory, but he suggests that in order to develop their usefulness an extension is advisable in the direction of providing dental treatment for actual and prospective mothers. It is found that the health of the mothers is seriously prejudiced by the presence of decaying teeth, which act as septic foci from which toxins are absorbed into the blood, and these have been proved to affect injuriously the unborn infant and also the milk of the nursing mother. There is already a dental clinic for school children, with a dentist and nurse conducting the work, and he suggests that arrangements should be made for two sessions at the antenatal clinic. Dr. Taylor would administer the necessary anesthetics, as he does in the case of the school children. The total expenditure, excepting a small sum for fillings, would not exceed £125 per annum, one-half of which would be payable by the Local Government Board. Dr. Taylor predicts that incalculable benefit would be conferred on the mothers and infants by this modest outlay. The health committee has agreed to this proposal.—*British Dental Journal*.

Determining the Length of the Bite.—

Each case of denture construction is a law unto itself, and no rule of averages, be it ever so inclusive, can possibly supplant or adequately supply the specific demands arising in the individual case. The rule that the length of the teeth should be established in accordance with the lips when in position of repose is no less impractical than is the rule of establishing the occlusal plane.

The misleading feature of this rule, by which we are supposed to determine the length of the teeth, is due entirely to the fact that the rule does not conform to the conditions imposed in nature. When the

muscles controlling mandibular movements are in a state of rest the lips normally are extended to their full length. The muscles controlling mandibular movements are not constantly contracted—nature could not tolerate a constant contraction of these muscles—and in their unfunctionating state the mandible hangs down to the extent of relaxation of the suspending muscles and tendons, and the teeth are not normally in occlusion. The reverse of this normal repose in lip position would be found when the teeth are occluded and the lips are compressed and much shortened. It is my idea that the latter position of the lips more nearly indicates the length of the bite when the teeth are in occlusion than does the position of the lips when the muscles are relaxed and at rest.—RUPERT E. HALL, *Dental Review*.

What to Expect and What Not to Expect from a Radiograph.—A radiograph will not tell whether a tooth is vital or devitalized unless the root is filled, or there is an apical infection or apical abscess. Some root-fillings are transparent to the radiograph, and therefore the roots appear unfilled. But even in such cases it has been found that filling materials of this character, or most of them, anyhow, are not good root-canal fillings, and it is advisable to replace them with something better, such as rosin and chloroform and gutta-percha, or chloro-percha and gutta-percha, pushing the chloro-percha through the apex.

Don't expect every radiograph to show whether a filling does or does not encroach upon the pulp. Sometimes the angle from which it is taken will make it appear that it does, and sometimes that it does not.

An X-ray will not show all apical infections. There may be apical infections in which the bone has not been destroyed. Do not expect the X-ray to show all fistulous tracts. Sometimes it will and sometimes it will not.

Unless two and sometimes three radiographs at different angles are taken, all the roots of the upper first or second molar will not be shown clearly. Unless two or more radiographs at different angles are taken, do not expect a radiograph to show whether or not a root is perforated.

Radiographs are supposed to show foreign bodies in the teeth and jaws, such as metal fillings, pieces of fillings, gutta-percha, pieces of cement, broaches, missing or forgotten roots, misplaced or fractured teeth, and cysts. When wires are placed in the root-canals it will show how far these are accessible, the

curvature of the root, and the best means of access. Also remember that chloro-percha and gutta-percha are the best root-fillings so far devised, because they may be pushed through the apical foramen without danger if aseptic precautions have been taken; also they will show clearly and distinctly in the radiograph.—A. M. NODINE, *Dental Summary*.

Dental Dispensary of Omaha.—The Free Dental Dispensary of Omaha has just rounded out the first year of its existence. The dispensary committee submits the following report of the work accomplished during the week of February 14th to 21st, the last week of the first year of its operation. This week is typical of others:

| | |
|----------------------------------------|-----|
| Examinations | 52 |
| Extractions | 112 |
| Amalgam fillings | 156 |
| Cement fillings | 99 |
| Silver nitrate treatments | 4 |
| Treatments | 72 |
| Prophylaxis | 34 |
| Anesthetics: | |
| Local | 1 |
| Nitrous oxid | 9 |
| Postoperative treatments | 7 |
| Orthodontia (return cases) | 15 |
| X-rays taken | 3 |
| Referred to free medical dispensary .. | 3 |
| Individual health talks | 62 |
| "Lavender Cross" button given | 32 |
| Toothbrushes, tubes of paste | 18 |

The report demonstrates very clearly the two distinct aims of the dispensary:

(1) That the mouth and teeth of each child who presents himself for service be given the treatment that will make him a cleaner, healthier child, thus giving him a fair chance in life. This is made possible by the dentists who donate a part of their time to work on the teeth of these children.

(2) That each child receives the instructions necessary to keep his mouth in good, clean condition, and that he be made to realize the importance of "Clean Teeth—Good Health."

For this educational phase of the work we depend on our office secretary, who explains the value of mouth hygiene, and presents each child with his toothbrush and his "Lavender Cross" button. Toothbrush drills are given to the children in public schools by the school nurses.

By each one doing his bit this institution is constantly turning out better boys and girls for Omaha.—*Omaha World-Herald*.

Technique for Cleaning and Filling Root-canals.—Having isolated a tooth and cleansed the surrounding tissues, the canals are then to be cleaned. A small broach is passed into the canal as a finder, measuring the approximate distance to an obstruction, and a fine Kerr root-canal reamer is used to open it as far as possible. This is followed by a medium-sized reamer of the same type, then a Kerr file is used—all of which takes only a short time, if proper care is used not to twist off the ends of such delicate instruments. After this the canal is ready for filling.

The use of cotton on broaches for drying canals should be avoided, as all debris can be removed and the canal cleansed as previously stated. The very nature of the cotton, and the practical impossibility of keeping the hands clean during such an operation, render the use of cotton on broaches just prior to placing the root-filling in position very dangerous, and, in fact, a rather slovenly method. A small glass tray with a glass top should be used to hold the canal points, which should always be immersed in alcohol, and, just prior to use, a few points placed on the edge of the tray to dry before insertion into the canal, the canal being dried by the use of the electric canal dryer, or in the absence of this instrument, a hot blast from a chip-blower will suffice. The canal is then moistened with eucalyptol and either chloro-percha or euca-percha compound is used and pumped into the canal, as far as is possible. This is followed by canal points, and instead of a root-canal plugger I use a short broach, and force this into the mass until it is soft, and if possible get a response from the patient, after which a larger point is used, the end cut off and burnished over the opening, and I have every reason to believe my work will prove satisfactory.—J. K. CONROY, *Dental Review*.

Advantages of Clasped Dentures.—(1) Cheapness of construction as compared with other forms of attachment for removable bridge work; (2) the absence of necessity for immediate destruction of tooth substance; (3) less strain upon supporting natural teeth.

The principal objection to clasps, of course, lies in the possible future destruction of tooth substance, but, viewed from all aspects, is it not the manifest duty of prosthodontists to apply at least some of their talents to the improvement of a class of work and a type of denture which is less expensive and more generally useful?

Cannot we now construct a clasp with the minimum of risk to the tooth which it en-

circles, and would it not be equally as permissible to cut a cavity and protect with a gold filling or inlay the surface which the clasp is to touch, as it is to remove a pulp and destroy a quarter or a half of a tooth, as is done for some styles of bridge work? Indeed, is it not time for a renaissance of clasp construction? I think it is.

After many years of keen observation, and after having utilized almost every form of attachment known to the profession, I now and here want to make a plea for a more general use of clasps in the construction of all forms of partial dentures, and wish to support this plea with this statement: I believe that a good clasp used where indicated, and well adapted to the supporting tooth, will in the long run do less injury, both in the way of destructive influence upon tooth structure and in the subsequent loosening of the tooth, as a whole, from stress and strain, than any other form of attachment now at our command.

That the full scope of advantages and possibilities may obtain, however, it is of course necessary, first, that clasps should be used only when indicated; second, that all of the requirements of a clasp must be observed to the fullest extent; and third, that the form must be favorable, and the adaptation to the supporting tooth good.—HART J. GOSLEE, *Dental Items of Interest*.

Anatomical Occlusion and Articulation in Artificial Dentures.—To secure this condition means that the artificial teeth should be so formed and arranged that they will occlude and articulate without undue interferences, balance and support the dentures against displacement under the stress of the forces of incision and mastication, guide the co-ordinating muscles in directing the movements of the mandible, and at the same time, in the positions or relations of articulation, provide spaces for food.

Teeth may be anatomically arranged by having an articulator capable of imitating all of the movements of incision and mastication of the mandible, and then have these movements under such control that we may utilize them for the perfect positioning and grinding of the teeth in anatomical relations as guided by esthetics, by the alveolar ridges, and the movements of the articulator.

Present teaching and practices are now wrong: (1) Because of faulty methods and articulators; (2) because the cusps of the teeth now upon the market are not long enough to permit meshing or interlocking so that in movements of the mandible they will reach and maintain contacts with their antagonists, provide adequate spaces for food,

and balance the dentures under the stress of the forces of mastication.

Teeth with deep angular cusps (guiding angle 45°), correctly arranged, balance the vertical and lateral or horizontal movements of the mandible, as typical to nature when in the stage of greatest efficiency; also definitely guide the co-ordinating muscles in directing the movements of the mandible, also typical to nature; provide spaces for food; balance and support the dentures in the process of incision and mastication against movements from their basal seat; and in case of displacement of the dentures, steady and guide their return to their normal position—comparable with the guiding and support-

ing influence of the rails of the railway track upon the railway coach, the rails the lower teeth (high cusps), and the wheels, their flanges (long cusps), the upper teeth. The train without the flanges upon its wheels to secure and guide its movements upon the rails (movements of the mandible in the case of a masticatory apparatus) would leave the track, not travel its intended course, and be a failure. Likewise may we justly and logically regard the principles involving the construction and uses of artificial dentures if we are to expect them to perform the function of incision and mastication efficiently, and not be failures.—RUPERT E. HALL, *Dental Review*.

OBITUARY

Dr. Isaac Howard Davis.

[SEE FRONTISPICE.]

DIED, at his home in Baltimore, Md., Friday, February 8, 1918, in his fifty-ninth year, ISAAC HOWARD DAVIS, M.D., D.D.S.

Dr. Davis was born at Dickenson, Montgomery county, Md., September 4, 1859, the seventh son of Isaac and Catharine (Miles) Davis. His grandfather came to America from Wales, and settled in Pennsylvania.

His early education was obtained in the county schools, where he afterward taught for four years before entering the University of Maryland to pursue his study for his medical and dental degrees. He was graduated with honors from both the dental and medical departments of the university in 1884 and 1885 respectively. Immediately following his graduation in medicine in 1885 he was made demonstrator of operative dentistry in the infirmary of the university, and at the same time began the practice of dentistry in Baltimore.

From the time of his graduation to the time of his death, a span of thirty-three years, Dr. Davis' participation in the affairs of his alma mater never ceased. From demonstrator of operative dentistry he was successively charged with the responsibility of associate professor of operative dentistry, professor of orthodontia, and in 1909 was made professor

of operative dentistry to succeed the late Prof. James H. Harris. All the duties accompanying the responsibility of these positions of importance were faithfully performed, even at times to his physical and financial detriment.

Dr. Davis' death marks the passing of the group who knew the dental department of the university from its founding to the present day. He entered its first class, and remained faithful to its progress and assisted it in every way possible. His last act was to lecture to the present senior class. Upon this occasion he sustained a fall which resulted in the condition ending in his death.

His love for the university was the dominant inspiration of his life. The betterment of the institution came before his individual interest, causing him to give unstintingly and unselfishly of his time and efforts, impairing his health and sacrificing personal gain in his endeavor to uplift the profession and build in his alma mater the future for his cherished dreams. A highly successful teacher, he was one by nature; master of his subject, clear, logical, penetrating in his presentation, and second to none in equipping his classes to meet the duties of their chosen profession.

Always of a spiritual trend of mind, he anticipated the ministry, but having abandoned the idea, the influence pervaded his entire life. He felt his mission among the

students to be a sacred one, while the character and uplift of the boys was a subject of real concern. His influence, as he wished it to be, was an unconscious one, preferring to typify by his life and embody in his actions the ideals he wished them to pursue. "He was nature's priest, and by the 'vision splendid' Was on his way attended."

Dr. Lyman Curtis Bryan.

DIED, at Lausanne, Switzerland, Monday, February 4, 1918, after a long and painful illness, in his sixty-fifth year, LYMAN CURTIS BRYAN, D.D.S.

Dr. Bryan was born on November 5, 1852, in Kentucky, U. S. A., and received his education at the University of Tennessee, Nashville, Tenn. He began the study of medicine and dentistry in 1876, later entering the Boston Dental College, from which institution he was graduated in 1880. Immediately after graduation, Dr. Bryan was made demonstrator of operative and clinical dentistry in the Boston Dental College.

In 1881, Dr. Bryan went to Basle, Switzerland, and established himself in the practice of dentistry, succeeding to the practices of Drs. Wright and Elliott, two prominent dentists of Basle. Dr. Bryan was highly successful in his practice, and attained considerable renown in the dental profession both in Switzerland and Germany.

He was an honorary member of the National Dental Association. He was an active member and at one time president of the following associations: The American Dental Association of Switzerland, Southwestern Section of the Central Society of American Dentists, Dental Association of Basle, and the European Advisory Board Association. In the year 1904 Dr. Bryan was honorary president for Switzerland of the Fourth International Dental Congress, which was held in St. Louis, Mo.

Dr. Bryan was throughout his career quite active in dental affairs, and made numerous contributions to the literature of dentistry. In the year 1909 he left Basle because of ill health, and went to Montreux with the intention of retiring to private life. Through business misfortune, however, Dr. Bryan found himself at the age of sixty years compelled to again take up active work. He

thereupon recommenced the practice of dentistry in Montreux, which he continued until about a year ago.

Dr. Bryan was married in 1883 to Miss Isabell S. Atwood, who for thirty-six years was in joy and sorrow his true and faithful wife.

The funeral services were held at the Montoie Cemetery, Lausanne, Switzerland, Wednesday, February 6, 1918, where his remains were interred.

Dr. Wm. Mortimer Zirkle.

DIED, Sunday, December 23, 1917, in Atlanta, Ga., following an operation for appendicitis, in his fifty-fifth year, WILLIAM MORTIMER ZIRKLE, D.D.S.

Dr. Zirkle was born at New Market, Va., in October 1863, the son of Caspar and Kate (Wendell) Zirkle. He obtained his early education in the public schools of Virginia, and began the study of dentistry in 1897 at the Southern Dental College, Atlanta, Ga., from which institution he was graduated in the year 1900. Dr. Zirkle, immediately on graduation, established himself in the practice of dentistry in Atlanta, Ga., and continued to practice there until the time of his death.

The death of Dr. Zirkle will bring a sense of keenest sadness to his hosts of personal and professional friends throughout the South.

Having labored long and earnestly to benefit humanity, and to do all in his power to elevate the dental profession, his physical strength commenced to ebb two years ago. His intimate friends feared it was the beginning of the end, and while, from time to time, he partially resumed his professional duties, he realized that the strain had been too great.

Though very retiring in his manner, and never seeking the recognition which was his just due on account of personal and professional attainments, he was for years a member of the faculty of the Southern Dental College, and at the time of his death was treasurer of the Georgia State Dental Society and a member of the Board of Dental Examiners for the State of Georgia. The Atlanta Society of Dental Surgeons was organized in 1905 at his suggestion, and he served as its first president. These positions he filled with

credit to himself and with honor to his chosen profession, and here as in every other department of his activities exemplified his sterling integrity and his professional attainments.

His death is a distinct loss to the dental profession in his city, his state, and the South.

Dr. Zirkle was married to Miss Carrie Brannan of Andersonville, Ga., who, with one son, Dr. Clyde B. Zirkle, survives him.

DR. WM. MORTIMER ZIRKLE.

He was an active member of the Masonic bodies from the Blue Lodge to the Shrine, and by his genial personality inspired confidence and affection in the hearts of all with whom he came in contact.

The funeral services were held from his late home on December 24th, and interment took place in the Westview Cemetery, Atlanta, Ga.

DELOS L. HILL.

ARMY AND NAVY DENTAL NEWS

Proposed Legislation.

Army Medical Department.

SENATE BILL 4168.

SENATOR Shields has introduced a bill (S. 4168) regulating and fixing the rank and compensation of the commissioned officers of the Medical corps and of the Medical Reserve corps of the army while in active service. It provides as follows:

That the Medical department of the army shall consist of one surgeon-general with the rank of major-general, who shall be chief of said department; six assistant surgeons-general, the assistant surgeons-general to be equally distributed in the grades of major-general and brigadier-general: the medical corps; the medical reserve corps; the dental corps; the dental reserve corps; the veterinary corps; the veterinary reserve corps; the commissioned officers of which shall be citizens of the United States; the nurse corps and contract surgeons authorized by law; the enlisted force of the medical department of the army, and the medical enlisted reserve corps, as now provided by law.

Commissioned officers of the medical corps below the rank of brigadier-general shall be proportionately distributed in the several grades as now provided by law.

The commissioned officers of the medical reserve corps shall be distributed in the several grades as in the medical corps of the army.

In time of war the President shall have authority to appoint in the grade of consultant, to be equally distributed in the grades of major-general and brigadier-general, such number of officers of the medical reserve corps as the interests of the service may demand: *Provided*, That reserve officers so appointed shall at no time exceed twenty in number.

Nothing in this act shall be held or construed so as to discharge any officer of the regular army or deprive him of a commission which he now holds therein.

Transfer to Medical Corps from Medical Reserve.

PROPOSED LEGISLATION.

REPRESENTATIVE DYER proposes to amend the National Defense Act so as to provide for transfer from the Reserve to Medical corps:

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled:

That hereafter the President shall be authorized to fill any vacancies that may occur in the commissioned *personnel* of the Medical department of the army of the United States by ordering such officers of the medical section, officers' reserve corps, and dental reserve corps, who shall have been in active service one year or more, to the army medical school or army dental school under such rules and regulations as shall be prescribed by the Secretary of War; and such officers so ordered, upon completion and satisfactory examination shall be commissioned first lieutenants in the Medical department, United States army, and be entitled to all the pay, promotion, and allowances of officers of like rank in the army of the United States, except that the rate of retirement shall be one-thirtieth of the present retirement pay as now prescribed by law for each year's active service as an enlisted man, contract surgeon, or as a commissioned officer in the army of the United States, medical section, officers' reserve corps, medical reserve corps, dental reserve corps, or organized militia in federal service: *Provided*, That at the age now prescribed by law for retirement every officer to be so commissioned shall have had not less than fifteen years' active service in any of the branches enumerated in this act: *Provided further*, That preference for appointment shall be given to those who have had the longest aggregate active service in the branches enumerated in this act.—*Army and Navy Register*.

Against Medical Corps Legislation.

THE War department is against the enactment of the Senate bill (3748) fixing the grades of the commissioned *personnel* of the Medical corps and the Medical Reserve corps of the army. The acting Secretary of War regards the proposed legislation as "highly undesirable," and has urged that it "be not favorably considered." Assuming that the number of medical officers on active duty will soon reach 70,000, Mr. Crowell states that "This would provide for 100 general officers, 800 colonels, 1600 lieutenant-colonels, and 17,500 officers in the lower grades." "The number of officers in the higher grades provided by this proposed legislation would be far in excess of the number authorized for service with troops, and would give greatly increased rank to officers serving with non-combatant troops over those serving with combatant forces, which is manifestly contrary to the prevailing views as to what is equitable and right." Attention is also called by Mr. Crowell to the fact that "All other sections of the reserve corps of the army limit the highest grade to that of major, and to include the medical reserve corps of the army in this proposed legislation would result in not only the abnormal and unwarranted promotions, but would give officers of the medical section of the reserve corps higher grades than provided for any other section of the reserve corps, which would be a manifest injustice."—*Army and Navy Register*.

Army Medical Department.

VACANCIES IN THE DENTAL CORPS.

WHILE nothing official has yet been vouchsafed in regard to the decision of the War department as to the total enlisted strength of the army which is to be the basis of the commissioned *personnel* of the Medical department of the regular establishment, it is understood that the ruling, which may be expected during the coming week, will announce this total enlisted strength as 286,000. There will be, accordingly, an excess of colonels and lieutenant-colonels, owing to the fact that the numbers in those grades as now existing were based on a strength of 300,000. The excess number will, of course, have to be absorbed, but as there are a number of retirements in prospect during the next few months the situation will not be a difficult one to adjust. There are now 883 officers in the Medical department, including those who have been recently recommended for appointment, and on the basis of the prescribed total of 1000 vacancies to be filled. The Dental corps, now consisting of 209 officers, is entitled to some

90 more in view of the fact that the *personnel* of that branch is founded on the total strength of the army estimated at 300,000 instead of the total enlisted strength. In the examination which was recently held, the results of which are to be made known in the next few weeks, it was announced that the candidates found qualified would be afforded the opportunity of appointment to the restricted degree of not more than three or four vacancies. A large number of candidates had previously applied for the privilege of taking the examination, and when it became known that the vacancies were so few in number many of them declined to enter the competition. Since then, it is promised, there have arisen nearly 100 vacancies to be filled, and probably there will be much discontent expressed when it is known that there were a larger number of vacancies than was at one time in prospect.—*Army and Navy Register*.

Additional Dentists for Divisions.

AUTHORITY has been given by the War department for increase of the allowance of dental *personnel* for the divisions about to depart for France. Such divisions will have 31 dental officers and 32 enlisted men as dentists' assistants, in place of the former allowance of 25 of each class. The allowance of dental officers as prescribed by law for the regular army is one per 1000 of the regular commissioned and enlisted *personnel* of the line and staff, and this ratio has been maintained in placing members of the dental reserve corps and of the dental corps of the national army on active service. The dentists—basing their estimates on the average in private practice—are advocating an allowance of three dental officers per 1000 of the *personnel* of the military establishment. The allowance of 31 dental officers to an overseas division gives less than two per 1000. A new class of recently appointed members of the regular dental corps and of the dental reserve corps commenced a two months' course of instruction at Fort Oglethorpe, Ga., on April 15th.—*Army and Navy Register*.

Competition in Training Camps.

EFFICIENCY RECORDS.

It is proposed to hold a dental efficiency record competition between the different training camps, based upon: The amount and class of dental treatment administered, dental study clubs, societies or meetings held, conduct of dental officers, such as moral or physical fitness; personal qualifications, such as neatness of appearance and social con-

duct among other officers; the equipment of dental operating rooms and care of same, or any other data on the general efficiency of the camps.

A questionnaire will be submitted by the executive council of the Association of Military Dental Surgeons for the division surgeon to fill out, and from these reports the executive council will select the winner. The winning camp will be given a banner with a suitable inscription.

Initiative on the part of the dental officers in camp in making the best suggestions, making the best of what they have, getting what is necessary and obtainable from the medical and quartermaster's corps, will also be considered—so it behooves the dental officers in camp to get busy.

The division surgeon will be invited to officiate, and note the above-mentioned points.—*Journ. Assoc. Military Dental Surg. U. S.*

Naval Student Reservists.

INSTRUCTIONS have been issued by the bureau of navigation to call to active duty those naval reservists now in an inactive status in order to continue courses at college. These men will be assigned to duty at the completion of the current school year, the only exceptions being medical and dental students who are enrolled in the hospital corps reserve, and who will not be called to duty this year until one year after graduation, as it is believed that during that year they will acquire valuable professional experience in civil life. Undergraduate medical and dental students will not be called out, as many schools are continuing their course through the vacation period, and undergraduates will doubtless want to accept internships in hospitals which have been depleted owing to the war. Graduate students of other colleges will be retained on active duty; undergraduates will be given training during the vacation period, and may again be released to resume

their studies next fall. Graduates who are called to duty will be examined with a view to determining their fitness for the various officer schools, especially graduates of technical schools. Undergraduates will also be examined for these schools, but if they enter the officer school or qualify for commission, they forfeit their privilege of returning to college. Undergraduates will be assigned to recruit training, and later will be placed in the patrol forces of the several naval districts.—*Army and Navy Register.*

Dental Service in the British Navy.

THE army dental service by reason of its numbers commands the greater share of our attention, but that the navy also has its difficulties must not be overlooked. The fact that dental surgeons serving afloat are duly commissioned officers, while their colleagues ashore are only civilians, has been brought before Parliament on several occasions during the past three years, and we are glad to learn is at last to be remedied by the granting of commissions in the Royal Naval Volunteer Reserve to all dental surgeons so employed. This we look upon as only a prelude to the granting of commissions on the strength of the royal navy, and to the establishment of a Royal Naval Dental Service. Naval dental surgeons tell us that the seamen's mouths are as much neglected and need as much attention as those of the British Tommy. We believe that the bluejacket is quite keen to have his teeth attended to, but that he is not very addicted to the use of the toothbrush which forms part of his kit. The denture work of the navy seems to need centralization, and arrangements should be made for the rapid supply and repair of dentures during the brief periods when the ships are in port. If this is not done, a useless expenditure of time and money takes place, owing to the sudden departure of ships and men from their harbors.—*Brit. Dental Journal.*

Work Done by the Canadian Army Dental Corps.

DENTAL OPERATIONS PERFORMED BY OFFICERS OF THE CANADIAN ARMY DENTAL CORPS IN ENGLAND AND FRANCE, FROM OCTOBER 1 TO DECEMBER 31, 1917; ALSO GRAND TOTAL OF WORK COMPLETED SINCE JULY 15, 1915.

J. ALEX. ARMSTRONG, Col.,
Director of Dental Services, O. M. F. of Can.

An Unusual War Injury.

In a recent issue of the *British Medical Journal*. Mr. Gordon Taylor of the Middlesex Hospital records a most interesting case. During the battle of the Somme a soldier was buried in his shelter by a large shell. He was dug out from among the debris in an unconscious state, and ultimately placed on a hospital barge, and thus conveyed to the base. When he recovered consciousness on the barge, one of his first requests was for the artificial toothplate which he had been wearing when he was rendered unconscious by the shell explosion. The denture—an upper one—was produced from his wallet by the attendant orderly, but the patient, remarking its size and the number of teeth, quickly declared his doubt as to its being his, or if it were, he assured those in attendance that it must have been broken, and that part of it was missing.

The patient had also shown some signs of a fracture of the skull, and to this was ascribed the difficulty in swallowing of which he complained. No radiogram was apparently taken, and he was speedily evacuated to England, and admitted into one of the auxiliary military hospitals at Eastbourne. The man's story led to an investigation of the denture, which showed clear evidence of having been fractured across its palatal and alveolar portions. Examination with the screen revealed the presence of a foreign body in the thorax, and an X-ray plate showed a denture with two teeth opposite the middle piece of the sternum. The use of Brüning's œsophagoscope fitted with a Hill's tube made it possible to obtain a good view of the offending denture, and it was easily extracted *per vias naturales* by means of an Irwin Moore's forceps.

The case is of interest in that a fracture of an upper dental plate was produced without any injury of the superior maxilla. Such an experience as this is interesting and valuable, in civil as well as in military practice. The unfortunate aspect of the case is the length of time which elapsed before the patient came under the skilled care of Mr. Gordon Taylor. It emphasizes the value of routine X-ray examination of all doubtful cases.—*Brit. Dental Journal*.

Personnel of Medical Department.

For the week ending March 8, 1918, the personnel of the medical department of the army included—

Medical Corps: 796, including 1 major-general, 66 colonels, 102 lieutenant-colonels, 177 majors, 2 captains, and 448 lieutenants.

Medical Reserve Corps: 17,654, including 1069 majors, 4063 captains, and 12,522 lieutenants; on active duty 14,283, including 942 majors, 3492 captains, and 9849 lieutenants. *Medical Corps National Guard:* 1243, including 11 lieutenant-colonels, 257 majors, 149 captains and 826 lieutenants. *Medical Corps, National Army:* 70, including 4 brigadier-generals, 12 colonels, 49 lieutenant-colonels, and 5 majors.

Dental Corps. 211. *Dental Reserve Corps,* 5114, of whom 1334 are on active duty. *Dental Corps National Guard,* 260.

Veterinary Corps, 24. *Veterinary Reserve Corps,* 1400, of whom 781 are on active duty. *Veterinary Corps National Army,* 294.

Sanitary Corps, 940, and *Ambulance Service,* 138, constitute the remainder of the commissioned personnel.—*Journ. A. M. A.*

Promotions.

Dental Reserve Corps.

THE following appointments (promotions) are announced (March 30th):

To be MAJORS: 1st Lieuts. Earl C. Branger, Henry W. Rich, and Guy P. Bannister.

To be CAPTAINS: 1st Lieuts. John P. Garriott, Jesse L. Meredith, Alphonse L. Senecal, William V. Thomson, Thomas M. Terry, Smith C. Tanner, Walter F. Clayton, Robert H. Nones, Jr., and Royal E. Wight.

Announced April 6th:

To be CAPTAINS: 1st Lieuts. Perry Haskell Phummer, Kenneth F. Smith, Austin R. Killian, John C. Gallagher, and Frank W. Gale.

Announced April 13th:

To be CAPTAINS: 1st Lieuts. James B. Davidson, Arthur Lankford, John F. Ackley, Rae P. McGee, Wm. C. Speakman, Stewart D. Ruggles, Gerald G. Burns, Harry B. Butler, Gregory P. Cassidy, James L. Clements, Roscoe L. Barber, George A. Hewey, Ozias Paquin, Jr., Nathaniel Barnard, Leonard G. Mitchell, Edward E. P. Sleppy, Frank D. Pierce, Robert R. Luce, Frank P. Gormley, John J. W. Ross, and Ivan E. Smith.

Assignments.

Army Dental Corps.

Week ending March 23d.

Major Rich'd B. Clark from duty in Hawaiian department to San Francisco.

The following from present duties to Fort Oglethorpe for duty as instructors: Majors Ben H. Sherrard and E. Henry Valentine.

The following to Fort Oglethorpe for course of instruction: Major Thomas L. Smith, 1st Lieuts. Alvin E. Anthony, Leslie D. Baskin,

Jacob L. Brause, Arthur T. Burchill, Albert S. Cumming, Frederick C. Daniels, Alvin D. Danheisser, Benjamin H. Dean, James E. Dean, Chester Denham, Melvin R. Eiche, Harold S. Embree, Raymond H. Fisher, Jerome L. Fritzsche, Dell S. Gray, Leroy P. Hartley, Wm. H. Holblitzell, Henry L. Hogan, Avery G. Holmes, Clarence R. Jacobson, George R. Kennebeck, Hooker O. Lindsay, Lewis W. Maly, James B. Manning, Neil J. McCollum, Roy R. Newman, James H. O'Reilly, Harold J. Parker, Adrian C. Ragan, Fletcher D. Rhodes, Fernando T. Rodriguez, Walter A. Rose, John A. Rowe, Roy C. Starr, Eugene A. Smith, Wm. B. Stewart, Robert L. Strickland, Richard F. Thompson, Lynn H. Tingay, and Walter D. Vail.

Week ending March 30th.

Col. Wm. H. Chambers from duty at Presidio of San Francisco to Fort McPherson, general hospital 6, for temporary duty.

Week ending April 13th.

Col. Wm. H. Chambers from duty at Presidio of San Francisco to Fort McPherson, general hospital, for duty.

Col. Julian R. Bernheim to report to Surgeon-general for duty in his office.

Leave for three months granted Maj. J. Craig King on surgeon's certificate.

1st Lieut. Wm. F. Wieck to Fort Oglethorpe for course of instruction.

Dental Reserve Corps.

Week ending March 23d.

Capt. Fred Tiesse, Jr., to Washington, 50th infantry camp, East Potomac Park, for duty.

The following to Fort Oglethorpe for course of instruction: Capt. Floyd E. West, 1st Lieuts. Guy P. Bannister, Wm. R. Beattie, Albert J. T. Beatty, Francis A. Boylan, Wm. Z. Carroll, Walter T. Clark, John F. Connolly, Donald D. Cornell, Thomas Crenshaw, Jr., James G. Crutchfield, Charles E. Davis, Joseph D. Eby, George H. Elliot, Max C. Frazier, Walton J. Graft, James F. Hannon, Edger T. Haynes, James H. Keith, Floyd D. Leach, Edward B. Lodge, Jerome B. Marshall, Walter F. Neuhoft, Arthur H. Nobbs, Henry W. Rich, George E. Roland, Wm. J. Stark, Roy A. Stout, Wm. V. Thomson, Harry M. Trafford, Raymond L. White and Walter L. Wilson.

Week ending March 30th.

Capt. Walter Sorenson to Fort McHenry, Md., general hospital 2, for duty.

A WAR NEED OF THE GOVERNMENT.

Stenographers and Typists Wanted—Men and Women.

UNITED STATES CIVIL SERVICE EXAMINATIONS.

THE United States Government is in urgent need of thousands of typewriter operators and stenographers and typists. All who pass examinations for the departments and offices at Washington, D. C., are assured of certification for appointment. It is the manifest duty of citizens with this special knowledge to use it at this time where it will be of most value to the Government. Women especially are urged to undertake this office work. Those who have not the required training are encouraged to undergo instruction at once.

with the Commission at Washington, D. C., at any time.

The entrance salary ranges from \$1000 to \$1200 a year. Advancement of capable employees to higher salaries is reasonably rapid.

Applicants must have reached their eighteenth birthday on the date of the examination.

For full information in regard to the scope and character of the examination and for application blanks address the U. S. Civil Service Commission, Washington, D. C.; or the Secretary of the U. S. Civil Service Board of Examiners at Boston, Mass.; New York, N. Y.; Philadelphia, Pa.; Atlanta, Ga.; Cincinnati, Ohio; Chicago, Ill.; St. Paul, Minn.; St. Louis, Mo.; New Orleans, La.; Seattle, Wash.; San Francisco, Cal.; Honolulu, Hawaii; or San Juan, Porto Rico.

JOHN A. McILHENNY,

President U. S. Civil Service Commission.

WASHINGTON, D. C.

EXAMINATIONS for the Departmental Service, for both men and women, are held every Tuesday in 450 of the principal cities of the United States, and applications may be filed

Preparedness League of American Dentists.

ORGANIZED UNDER THE AUSPICES OF THE N. D. A.

THE DENTAL COMMITTEE OF THE GENERAL MEDICAL BOARD, WHICH IS THE AGENCY FOR THE MEDICAL AND DENTAL PREPAREDNESS IN THIS WAR EMERGENCY, HAS MADE IT POSSIBLE FOR EVERY DENTIST IN THE UNITED STATES TO ASSIST IN THE WORK, UNDER THE SUPERVISION OF LIEUT. WM. A. HECKARD, D.R.C., U.S.A., STATIONED AT 50 EAST 42D ST., NEW YORK, N. Y.

Preparedness League Notes and News.

By R. OTTOLENGUI, *Publicity Committee.*

REPORT FROM THE PRESIDENT.

OUR NEXT MOVE.

We do not want members of the League to get the idea that the great drive now going on to help make our National Army dentally fit is the sole object of our organization. It is but one of a series of our activities. The development of our dental motor car is a signal illustration of the great possibilities before us.

Those of us who are not commissioned, and who continue in civil practice, must devote our energies to preparing to give expert services to our soldiers who have been injured in battle. We will find ourselves in need of all the skill we can summon, therefore I would impress upon our members the great advantage of forming sectional units of the League throughout the whole country for the study of war oral and dental surgery. We are proud to say that our dental reserve is overfilled, and service in that direction is amply provided for. However, if later on more are needed, the study course will be better prepare us. I therefore strongly urge the promotion of this object, and point with pride to the splendid record the League has already made in that direction. More than one hundred sectional units have given such a course, which has been the means of assisting several hundred to pass examinations to the Reserve corps, as well as promoting their advancement to higher commissions and positions in the service.

"Knowledge is power," and is the best weapon at our command to overcome the results of disaster. It is our duty to marshal our forces as rapidly as possible for this object, as already our boys are beginning to return sadly in need of our best service, and

the great battle which has been fought will bring thousands upon thousands to whom we must minister. Every dentist, whether or not a member of the League, should make this a personal matter, and if not near a League unit, interest himself in forming one in his neighborhood, and we will gladly supply all information and give the needed assistance.

Awaken to this call and put your shoulder to the wheel, otherwise *you may realize later that you have not done all you might have done for your country.* By communicating with the office of the president, 131 Allen st., Buffalo, N. Y., we will give you full instruction as to the procedure.

LECTURE AND SLIDES.

The League has prepared a synopsis lecture accompanied by slides showing cases of Plastic and Oral Surgery before and after treatment, a series covering our Free Dental Activities, and a third, showing our new Dental Motor Car.

Twenty-five sets have been distributed to different state directors for use by sectional units of the League and all other societies. We urge their use at state society meetings. The laity, also, will be interested. Assignments may be made by your state director or through the office of the president, 131 Allen st., Buffalo, N. Y.

IMPORTANT NOTICE.

It has come to the attention of the President of the League that a pamphlet is being circulated advising our members to charge selective service men who are able to pay for the service necessary to make them dentally fit.

This pamphlet is *spurious*, and the originators deserve no better treatment than in-

ternment during the war as cohorts of the Kaiser. It is but another vain attempt to abort the principles upon which the League is founded, and which will live for ages after the perpetrators of this un-American and despicable subterfuge have become naught but a blotch of mold upon our fair soil and the unfairly acquired gain has been dissipated without benefit to themselves or their families.

I trust all loyal dentists will exert themselves to give this stigma the lie by strictly adhering to the only principle that can make our organization live and be of vital importance to humanity and our country in this great crisis.

J. W. BEACH, *President.*

REPORT FROM THE DIRECTOR-GENERAL.

* * * * *

DENTAL REQUIREMENTS AND EMERGENCY WORK.

There seems to be a misunderstanding on the part of some as to what the dental requirements are to fit a man for general military service. He must have six opposing incisors and six opposing masticating teeth (either bicuspid or molars). These bicus-

pids or molars may be all on one side or part on each side, but there must be at least three above and three below, each of which must touch some tooth on the opposite jaw.

The most important thing to do for these men is to rid their mouths of bad roots and infected teeth, or any tooth having a history of periodical abscess. After the mouths are freed from infection and the gums healed, plates can be made by members of the League who desire to do so, or they can be made after reaching the cantonments, if the officer in charge deems it necessary. The mouths, however, must *first* be made free from infection. Then, if possible, any large cavities in the remaining teeth should be filled and the teeth cleaned.

The lack of the minimum number of teeth (six and six) does not excuse any man from *military* service, but only from general military service. The man who has less teeth than the minimum required for *general* military service can be accepted (if otherwise fit) for limited military service, even if he has *no* teeth. These men for limited military service will cook food, drive wagons and auto trucks, carry supplies, work in factories, shops, or storehouses, etc.

CHAS. F. ASH, *Director-general.*

All ethical dentists who are not yet members of the PREPAREDNESS LEAGUE are earnestly requested to fill out the Application Blank below and mail to the Treasurer, DR. L. M. WAUGH, with \$1.00 membership fee.

APPLICATION BLANK

TO THE

Preparedness League of American Dentists.

Being an ethical dentist, I hereby make application for **ACTIVE MEMBERSHIP** in the Preparedness League of American Dentists, which entitles me to all the benefits and privileges of the organization.

Enclosed find \$1.00 (One Dollar) membership fee, including official button. No dues or assessments.

Signed

Please write name
and address plainly.

(Inclose professional card.)

MAKE CHECK PAYABLE TO

L. M. WAUGH, 576 Fifth Ave., New York City.

SOCIETY NOTES AND ANNOUNCEMENTS

NOTICES should reach the Office of the DENTAL COSMOS *not later* than the 11th or 12th of the month preceding that of publication.

1378 Beacon st., Brookline, Mass.

H. W. DOREMUS,

Orange and Seventh sts., Newark, N. J.

Delta Sigma Delta Fraternity.

THE thirty-fourth annual meeting of the Supreme Chapter of Delta Sigma Delta Fraternity will be held in the Florentine Room of the Congress Hotel, Chicago, on Monday, August 5, 1918, at 9 A.M.

The regular order of business will be pursued, to be followed by initiatory exercises in the afternoon.

Headquarters of the Fraternity will be at the same hotel, at which place the annual

banquet will also be held in the evening in the Gold Room. Those expecting to attend the banquet will greatly facilitate the work of the Dinner Committee by notifying them at once.

By order of the Supreme Chapter.

HY. W. MORGAN, *Supreme Gr. Master.*

R. HAMILL D. SWING, *Supreme Scribe.*

American Society of Orthodontists.

THE eighteenth annual meeting of the American Society of Orthodontists will be held August 1, 2, and 3, 1918, at the Edgewater Beach Hotel, Chicago, Ill.

This will be an excellent meeting. It is advisable to make your reservations early.

F. M. CASTO, *Sec'y.*

Rose Bldg., Cleveland, Ohio.

National Association of Dental Faculties.

THE next annual meeting of the National Association of Dental Faculties will be held in the Green room of the Congress Hotel, Chicago, Ill., August 2, 1918, at noon. The Executive Committee will meet at 10 A.M. on the 2d. The meeting will continue through August 3d.

CHAS. C. ALLEN, *Sec'y.*

N. W. cor. 10th and Troest, Kansas City, Mo.

North Dakota State Dental Association.

THE North Dakota State Dental Association will hold their annual meeting at Grand Forks, N. D., May 21 and 22, 1918.

ALBERT HALLENBERG, *President.*

Fargo, N. D.

OLON CRUM, *Sec'y.*

Fargo, N. D.

Eastern Association of Graduates of the Angle School.

THE annual meeting of the Eastern Association of Graduates of the Angle School of Orthodontia will be held at the Hotel Vanderbilt, New York City, on Monday and Tuesday, May 6 and 7, 1918.

FREDERIC T. MURLESS, JR., *President.*

Hartford, Conn.

E. SANTLEY BUTLER, *Sec'y.*

576 Fifth ave., New York City.

Massachusetts Dental Society.

THE fifty-fourth annual meeting of the Massachusetts Dental Society will be held in Boston, Mass., on Wednesday, Thursday, and Friday, May 1, 2, and 3, 1918, at the Massachusetts Charitable Mechanic Association Building on Huntington ave.

WALDO E. BOARDMAN,

Chairman Ex. Com.

J. ARTHUR FURBISH, *Sec'y*,

400 Marlboro st., Boston, Mass.

Iowa State Dental Society.

THE fifty-sixth annual meeting of the Iowa State Dental Society will be held in Des Moines, Iowa, May 7, 8, and 9, 1918. An excellent program has been prepared, including seminars, papers, and clinics. A cordial invitation is extended ethical members of the profession from out of the state to attend any or all of these sessions.

E. R. SWANK, *Sec'y*, Panora, Iowa.

Illinois State Dental Society.

THE fifty-fourth annual meeting of the Illinois State Dental Society will be held at Bloomington, Ill., May 14, 15, 16, and 17, 1918.

J. E. HINKINS, *Pres.*, Chicago, Ill.

J. P. LUTHRINGER, *Sec'y*, Peoria, Ill.

North Carolina Dental Society.

THE North Carolina Dental Society will meet on June 19 to 21, 1918. Headquarters, Oceanic Hotel, Wilmington, N. C.

W. T. MARTIN, *Sec'y*,

Northern Ohio Dental Association.

THE annual meeting of the Northern Ohio Dental Association will be held June 6, 7, and 8, 1918, at Toledo, Ohio.

C. H. CLARK, *Sec'y*, Youngstown, Ohio.

Northwestern University Dental School.

THE Northwestern University Dental School Alumni Association will hold the annual Home-coming Clinic, 31 W. Lake st., Chicago, Ill., on June 10 and 11, 1918. Special features have been provided which will insure a successful and interesting meeting. Make your arrangements now.

M. M. PRINTZ, *Sec'y*,

4235 Lake Park ave., Chicago.

American Medical Association.

Section on Stomatology.

Following is the program for the American Medical Association, Section on Stomatology, for the meeting to be held in Chicago, June 11 to 14, 1918:

Chairman's Address. Dr. Frederick B. Noyes, Chicago.

(1) "Chanere of the Lip Following Injury with Dentist's Emery-Disk." Dr. Adelbert M. Moody, Chicago.

(2) "An Analysis of Two Hundred Cases of Malignant Diseases in the Oral Cavity by Electro-thermic Methods, or in Combination with Operative Surgery, X-rays, or Radium." Dr. Wm. L. Clark, Philadelphia, Pa.

(3) "Treatment of Epithelioma of the Jaws and Cheek with Heat and Radium." Dr. Gordon B. New, Rochester, Minn.

Discussion—Dr. Albert T. Ochsner, Chicago, Ill.

(4) "The Lipoids of Tumors of the Dental System." Dr. Kaethe W. Dewey, Chicago, Ill.

(5) "The Genesis of the Epithelial Débris in the Peridental Membrane, Nasmyth's Membrane, and the Granular Layer of Tomes." Dr. Eugene S. Talbot, Chicago, Ill.

(6) "Additional Roentgenographic Studies of Infections of the Maxillary Bones." Dr. Arthur D. Black, Chicago, Ill.

(7) "Microscopic Studies of Diseased Peridental Tissues, Illustrated by Stereopticon." Dr. Edward H. Hatton, Chicago, Ill.

(8) "Absorption of the Roots of Teeth." Dr. Herbert A. Potts, Chicago, Ill.

(9) "Neuralgia Dentalis." Dr. Kurt H. Thoma, Boston, Mass.

(10) "Longitudinal and Transverse Sectional Views of the Accessory Sinuses of the Human Cranium, Cut Parallel, and at Right Angles to the Nasal Septum." Dr. Geo. Edward Fell, Chicago, Ill.

The officers of the section cordially invite those who are interested in the program to be present, and to take part in the discussions.

FREDERICK B. NOYES, *Chairman*,

EUGENE S. TALBOT, *Sec'y*.

Dental Society of the State of New York.

THE fiftieth anniversary of the Dental Society of the State of New York will be held at Saratoga Springs, N. Y., June 13, 14, and 15, 1918. The society will endeavor to present a literary, clinic, and social program for the benefit of the profession, in keeping with its golden anniversary. A cordial invitation is extended to all members of the National Dental Association. For further information write

A. P. BURKHART, *Sec'y*,
52 Genesee st., Auburn, N. Y.

Georgia State Dental Society.

THE semi-centennial meeting of the Georgia State Dental Society will be held in Atlanta, Ga., June 12, 13, and 14, 1918, when this society will celebrate its fiftieth anniversary.

Florida State Dental Society.

THE Florida State Dental Society will hold its next annual meeting at the Atlantic Beach Hotel, Atlantic Beach, Fla., on June 20, 21, and 22, 1918, where fishing, golfing, and surf bathing is unsurpassed.

A fine program is being planned. All ethical practitioners of this and other states invited.

For further particulars address

D. D. CREWS, *Sec'y*,
Fort Myers, Fla.

Maine Dental Society.

THE fifty-third anniversary meeting of the Maine Dental Society will be held in the City-hall, Portland, Me., June 26 to 28, 1918.

I. E. PENDLETON, *Sec'y*,
Lewiston, Me.

Northeastern Massachusetts Dental Society.

THE annual meeting of the Northeastern Massachusetts Dental Society will be held at the New Ocean House, Swampscott, Mass., Wednesday and Thursday, June 26th and 27th. Finest hotel on the North Shore. All ethical members of the profession are cordially invited. Hotel rates one-half: \$5.00 per day.

HOWARTH STANSFIELD,
70 Merrimac st., Haverhill, Mass.

Postgraduate Dental Meeting:

Alabama—Mississippi—Texas—
Louisiana.

(1) *Place of meeting.* New Orleans, at the Grunewald Hotel.

(2) *Date.* To avoid interfering with dental college exercises and dental examining board meetings, and to be assured of pleasant weather, June 3, 4, 5, and 6 were selected.

(3) In order to give each member an equal opportunity to get all that is possible and not congest the meeting the membership will be limited to 350 members.

(4) Membership cards will be issued only to members in good standing in their state dental societies, and to dentists in the army and navy dental corps.

(5) The registration books will be closed May 27th (one week before the meeting) to all except members of the army and navy dental corps.

(6) *Fee.* Owing to increased cost of postage and stationery and all other expenses, the membership fee to the general meeting will be ten dollars for each member. Special courses following the general meeting, fifteen dollars for each course per member.

(7) No one will be issued a special course card unless he has registered for the general meeting.

The subjects chosen to be taught at the next meeting will be as follows:

"Nerve Blocking." Dr. Arthur E. Smith, Chicago.

"Technique of Root-canal Preparation, Treatment, and Filling." Dr. Elmer S. Best, Minneapolis.

"Full Upper and Lower Dentures." Dr. Rupert E. Hall, Chicago.

"Exodontia." (Instructor to be selected.)

General Chairman—J. J. Sarrazin, 424 Godechaux Bldg., New Orleans, chairman Committee on Interstate Relations.

General Secretary—Leo C. Dempsey, 943 Jackson ave., New Orleans.

Ask yourself the question, Can I afford to miss this meeting? Send your application for membership to the Four States Postgraduate meeting, with your check for ten dollars, to your state chairman for indorsement and transmission by him to Dr. L. C. Dempsey, the general secretary. Members of the Louisiana State Dental Society can apply direct to Dr. Dempsey with membership fee inclosed.

J. P. WAHL, *Ch'man Publicity Com.*,
1135 Maison Blanche, New Orleans, La.

Tennessee State Dental Association.

THE fifty-first annual meeting of the Tennessee State Dental Association will be held in Nashville, Tenn., June 17, 18, and 19, 1918.

GEO. L. POWERS, *Sec'y*,
Paris, Tenn.

South Carolina State Dental Association.

THE annual meeting of the South Carolina State Dental Association will be held at the Jefferson Hotel, Columbia, S. C., June 27, 28, and 29, 1918.

W. BUSEY SIMMONS, *President*,
ERNEST C. DYE, *Sec'y*.

Kentucky State Dental Association.

THE next annual meeting of the Kentucky State Dental Association will be held at Lexington, Ky., June 13, 14, and 15, 1918. An "amalgam program" of special interest.

Address all correspondence to

W. M. RANDALL, *Sec'y*,
1035 Second St., Louisville, Ky.

Washington State Dental Society.

THE Washington State Dental Society will hold its next meeting in Spokane, Wash., June 27, 28, and 29, 1918.

A. STARKE OLIVER, *President*,
FRANK B. LYNOTT, *Sec'y*,
249 Peyton Bldg., Spokane, Wash.

New Jersey State Dental Society.

THE forty-eighth annual convention of the New Jersey State Dental Society will be held on July 17, 18, and 19, 1918, on Young's Million Dollar Pier, Atlantic City, N. J.

The entire convention will be held on the pier. Machinery Hall will be used for the exhibits. Those who attended last year will remember the magnificent display of dental goods, and Dr. S. I. Callahan of Woodstown, N. J., chairman of the Exhibit Committee, with 25,000 square feet of space, has promised an exhibit greater than that of 1917.

The Essay Committee under the direction of Dr. C. M. F. Egel of Westfield, will present two or three essayists of prominence—names and subjects to be announced.

All meetings for the presentation of papers as well as the business meetings will be held in the Greek Temple, out on the pier.

The headquarters of the society will be at

the pier entrance. Mail may be directed to exhibitors, clinicians, or members in care of the Secretary New Jersey State Dental Society, Young's Million Dollar Pier.

A cordial invitation is extended to ethical practitioners.

JOHN C. FORSYTH, *Sec'y*,
430 E. State St., Trenton, N. J.

California State Dental Association.

THE California State Dental Association will hold its regular annual session for the year 1918 in San Francisco, July 8 to 13, 1918.

We will conduct our meeting this year on the Oklahoma plan, and feel that we can assure all who attend a pleasant as well as a profitable meeting. Further information may be obtained by addressing

JOHN E. GURLEY, *Sec'y*,
350 Post st., San Francisco.

Texas Board of Examiners.

THE next regular examination of the Texas State Board of Dental Examiners will be held in San Antonio, Texas, beginning June 17, 1918, at 9 A.M. No diplomas exchanged; no reciprocity.

The application fee of \$25 should be in the hands of the secretary not later than June 12th. For further particulars and application blanks address

HARRISON B. CAVE, *Sec'y*,
810-14 Wilson Bldg., Dallas, Texas.

Massachusetts Board of Examiners.

A MEETING of the Massachusetts Board of Dental Examiners will be held in Boston, Mass., June 22 to June 29, inclusive, 1918, for the examination of candidates for registration. All applications must be in the hands of the secretary on or before June 13th. For further information address

GEORGE H. PAYNE, *Sec'y*,
29 Commonwealth ave., Boston, Mass.

Connecticut Dental Commission.

THE Dental Commissioners of Connecticut will meet at Hartford, June 20, 21, and 22, 1918, to examine applicants for license to practice dentistry, to examine applicants for dental hygienist's license, and to transact any other business proper to come before them. For blanks and further information, address

EDWARD ERFLE, *Recorder*,
902 Main st., Hartford, Conn.

Washington Board of Examiners.

THE Washington State Board of Dental Examiners will hold their next meeting at Seattle, Wash., May 30 to June 5, 1918. Address all communications to

FRANK B. LYNOTT, *Sec'y*,
249 Peyton Bldg., Spokane, Wash.

Maryland Board of Examiners.

THE Maryland State Board of Dental Examiners will meet for examination of candidates for certificates in Baltimore, on May 30 and 31, 1918, at the Dental Department of the University of Maryland at 9 A.M.

For application blanks or further information apply to

F. F. DREW, *Sec'y*,
701 N. Howard st., Baltimore, Md.

California Board of Examiners.

THE next examination by the Board of Dental Examiners of California for a license to practice dentistry in that state will be held in the City of San Francisco, beginning on the 23d day of May 1918, at 9 A.M.

This examination will be followed by an examination in Los Angeles, beginning on the 10th day of June 1918, at 9 A.M.

All applications for examination must be filed with the board on the morning of the day set for beginning the examination (May 23d in San Francisco and June 10th in Los Angeles). Each application must be accompanied by the fee of \$25, necessary credentials (diploma and license from other states, testimonials of good moral character), and a recent unmounted photograph of the applicant.

By order of the Board of Dental Examiners of California.

C. A. HERRICK, *Sec'y*,
133 Geary st., San Francisco

Mississippi Board of Examiners.

THE Mississippi Board of Dental Examiners will hold its next annual meeting at the State Capitol building in Jackson, on the third Tuesday in June 1918, at 8 A.M. Fee for examination \$10. Diploma from recognized school and certificate of moral character required. No reciprocity or interchange. For further information, address

B. J. MARSHALL, *Sec'y*,
Marks, Miss.

Iowa Board of Examiners.

THE next meeting of the Iowa State Board of Examiners will be held at Iowa City, Iowa, commencing June 3, 1918, at 9 A.M.

For further information address

J. A. WEST, *Sec'y*,
417 Utica Bldg., Des Moines, Iowa.

Wisconsin Board of Examiners.

THE Wisconsin State Board of Dental Examiners will hold their spring examination, June 17, 1918, at the Marquette College, Ninth and Wells sts., Milwaukee, Wis. All applications must be in the secretary's hands thirty days before examination.

F. A. TATE, *Sec'y*,
Rice Lake, Wis.

South Carolina Board of Examiners.

THE annual meeting of the South Carolina Board of Dental Examiners will be held at The Jefferson, Columbia, S. C., beginning promptly at 9 o'clock, Monday morning, June 24, 1918.

All applications must be in the hands of the secretary by June 14th. Application blanks and full information may be obtained by addressing

R. L. SPENCER, *Sec'y*,
Bennettsville, S. C.

Pennsylvania Board of Examiners.

THE next examination of the Pennsylvania Board of Dental Examiners will be held in Philadelphia and Pittsburgh on Wednesday, Thursday, Friday, and Saturday, June 12, 13, 14, and 15, 1918.

The examination in practical work will be in the Evans Dental Institute, 40th and Spruce sts., Philadelphia, and the University of Pittsburgh, Pittsburgh, on Wednesday, June 12th. The examination in operative work will be held at 8.30 A.M. and the prosthetic work at 1.30 P.M. Applicants are required to furnish all instruments and a patient for the operative work.

The theoretical examination will be held in Musical Fund Hall, Philadelphia, and College of Pharmacy, Pride and Bluff sts. Pittsburgh, beginning at 9 A.M. on Thursday, June 13th.

Application papers can be secured from the department of Public Instruction, Harrisburg.

ALEXANDER H. REYNOLDS, *Sec'y*,
4630 Chester ave., Philadelphia.

Indiana Board of Examiners.

THE next meeting of the Indiana State Board of Dental Examiners will be held at the State-house, Indianapolis, June 17th to 22d inclusive. Applications and other information may be obtained by addressing.

H. C. MCKITTRICK, *Sec'y*,
Indianapolis, Ind.

Michigan Board of Examiners.

THE next meeting of the Michigan State Board of Dental Examiners will be held at the Dental College, University of Michigan, Ann Arbor, Michigan, June 17 to 22 inclusive. Applications and other information may be obtained by addressing

B. S. SUTHERLAND, *Sec'y*,
Owosso, Mich.

Rhode Island Board of Registration.

A MEETING of the Rhode Island Board of Registration in Dentistry for the examination of candidates will be held in the State-house, Providence, R. I., June 18, 19, and 20, 1918. Applications, accompanied with the proper fee, should be in the hands of the secretary by June 11th.

For further information address

ERNEST A. CHARBONNEL, *Sec'y*,
139 Mathewson st., Providence, R. I.

New Jersey Board of Registration.

THE State Board of Registration and Examination in Dentistry of New Jersey will hold their annual meeting and examination in the Assembly chamber, at the State-house, Trenton, N. J., on June 24, 25, 26, 27, and 28, 1918. License fee \$25, re-examination \$10.

Applications must be filed complete ten

days before the date of the examinations. Address all communications for further particulars to

JOHN C. FORSYTH, *Sec'y*,
430 E. State st., Trenton, N. J.

North Carolina Board of Examiners.

THE next meeting of the North Carolina State Board of Dental Examiners will be held at Wrightsville Beach, Wilmington, N. C., beginning promptly at 9 o'clock on Monday morning, June 17, 1918. For further information and application blanks address

F. L. HUNT, *Sec'y*,
Asheville, N. C.

Maine Board of Examiners.

THE Maine Board of Dental Examiners will hold their regular examination, beginning July 1, 1918, at 8.30 A.M., at the State-house.

All applications and fees, \$20, must be in the hands of the secretary by June 21, 1918.

The examination for DENTAL HYGIENISTS will be given at the same time; fee \$10.

WILL S. PAYSON, *Sec'y*,
Castine, Maine.

South Dakota Board of Examiners.

THE next meeting of the South Dakota State Board of Dental Examiners will be held at Sioux Falls, S. D., beginning promptly at 9 o'clock, Monday morning, July 1, 1918.

All applications must be in the hands of the secretary by June 24th. Fee for examination \$25. No reciprocity or interchange. Full information and application blanks may be received by addressing

L. S. SPENCER, *Sec'y*,
Watertown, S. D.

ORIGINAL COMMUNICATIONS

Replanting *vs.* Apicoectomy.

By C. EDMUND KELLS, D.D.S., New Orleans, La.

[Copyright 1918]

IT is undoubtedly safe to say that the operation of apicoectomy is quite "the thing" nowadays, and is, in fact, a fad with many up-to-date operators. It is to be seen at clinics, in the "movies," and, taken all in all, is always most interesting to see, staged as it usually is with the accompanying dramatic accessories of *so-called* asepsis.

But, "coming down from the clouds," as it were, will the operation, as usually performed and as *invariably seen* by the writer, stand analysis, and how will it compare with the apparently neglected operation of replanting for the accomplishment of the same purpose?

From the operations the writer has witnessed, and from what he has read, the methods of procedure in this operation may be divided into three classes:

(1) The root-canal or canals, as the case may be, are first thoroughly (?) filled, after which the root-ends are amputated and smoothed off.

(2) The root-ends are amputated before the canals are filled, and then the

ends of the roots are drilled out, and the ends of the canals filled with aseptic amalgam to a limited depth only.

(3) The teeth are taken as they come, the root-ends are amputated, the canals are left as found—good, bad, or indifferent, as the case may be—and the case dismissed, probably never to be seen or heard of again.

Let us now consider these various methods inversely as they have been enumerated.

Class 3. This technique needs no criticism. It stands condemned upon its face, and yet the writer has seen just such methods practiced.

Class 2. Does it not appear impossible to amputate the septic end of a septic tooth, drill up or down, as the case may be, into a septic canal, and fill this *septic end* with *aseptic* amalgam (leaving the balance of the canal and pulp chamber to be filled subsequently), and leave the tooth in a satisfactory condition? The only way to convince doubters of the soundness of this method would be to in-

sert septic teeth in a plaster model to simulate natural conditions, operate upon these teeth in the manner described, and then make bacteriological tests of the teeth. But where is the operator who pursues this method who will subject his work to such a test?

Class 1. This method should undoubtedly appeal to the more conservative operator as being the most rational of all, and yet its weak spot lies in the difficulty

FIG. 1.

of filling the root-canals satisfactorily to their very ends. The writer contends that if the canals are thus filled, the trouble beyond the end of the root will usually be taken care of by nature, and consequently, no apicoectomy will be needed. As proof of this contention the skiagraphs, in Fig. 1, showing a case before and after treatment, are submitted.

More often than not the root-canals cannot be satisfactorily prepared and filled, and in these cases apicoectomy could not possibly produce satisfactory results. It has been the writer's privilege to see, in the course of regular practice, a few patients from other cities who have had roots "apicoectomized" by some of the best-known men in the country, and very rarely have the results been satisfactory. It may be a coincidence, of course, but the facts remain just the same.

REPLANTING.

It has been shown that apicoectomy is most likely to succeed where it is least indicated, if not wholly unnecessary, and that where most needed its failure is assured. On the other hand, replanting offers the best chance of saving just such

teeth as apicoectomy cannot save, and which otherwise must be lost.

The writer's clinical experience with this operation dates back to November 1880, when his first case was undertaken, so that he has had some opportunity for the observation of the success of the operation. Success, however, is a relative term. What one operator might call a satisfactory result another might call a failure.

The writer considers that any natural tooth that is conserved for a period of five years, either by replanting or implanting, should be considered a satisfactory operation, and when his records show that few *replanted* teeth have failed before ten years of use, he believes that replanting is justifiable in any case that appears at all hopeful, and in some that might be classed as hopeless.

PROGNOSIS.

Moreover, when we consider that a lower molar which was replanted in June 1891 by the *crude methods then in vogue*, lasted nineteen years, and many others have lasted more than fifteen years, why

FIG. 2.

can we not hope that by the more careful technique now employed, our present operations should last even longer than that? The writer does not hesitate to prophesy that when some of our *able operators* tire of apicoectomy because of its non-success, and turn their attention to replanting, new methods will be devised which will revolutionize the operation to such an extent that instead of having the periodontal membrane destroyed, and a

tooth held in place by a process of ankylosis, as has usually occurred in the past—and which very process leads to the ultimate loss of the tooth through its destructive forces—this membrane will be preserved, the tooth again held in its socket by normal gomphosis, and its permanence assured. That this result has already been accomplished in occasional instances is the sincere belief of the writer.

A skiagraph of the molar just referred to is shown in Fig. 2. It is a reproduction of an untouched film, and was taken many years after the tooth was replanted. The periodental membrane is distinctly shown.

LIMITATIONS OF THE OPERATION.

It must be conceded that replanting is naturally best adapted to tapering, single-rooted teeth, although replantation of lower molars, when their roots are neither divergent or curved, may be safely undertaken. The crushing of the crown or breaking of the root in such a manner as to render replanting impossible is a contingency which must always be reckoned with.

DESCRIPTION OF THE AUTHOR'S METHOD OF REPLANTATION.

Replanting, as *now* practiced by the writer, will next be described:

Making the splint. Usually, before the time reserved for the operation proper, an impression is taken of the tooth to be operated upon, together with one or more teeth upon each side, and a splint is struck up of No. 35 gage (B. & S.) pure gold. When the patient returns this is burnished to the teeth, and as well as possible into the interdental spaces. It is carefully removed to prevent springing, and a small amount of 22-k. solder flowed at each of the interdental depressions away from the incisal edge, both labially and lingually, which stiffens the splint materially. It is again burnished upon the teeth, and then laid away until ready for use.

Preparation:

(1) Every effort is made to have as clean an operation as possible. Laboring under no illusion, no attempt is made to stage "surgical asepsis."

(2) The heads of the patient, operator, and assistants are covered with clean—not sterile—caps. No gowns are worn.

(3) The towel placed on the patient is clean, but not sterile.

(4) The extracting forceps, lancets, curets, and an abundance of tweezers and mouth mirrors, and whatever other instruments may be needed, are sterilized

FIG. 3.

in a formaldehyd sterilizer, while towels, tape, and floss silk, small glass beakers, etc., are thoroughly sterilized according to *surgical custom*, in a Rochester combination sterilizer.

(5) An irrigating device (Fig. 3) with its rubber tubing and suitable tip is sterilized and charged with warm normal salt solution and kept warm.

The technique:

(1) The region is anesthetized by means of novocain-suprarenin.

(2) While realizing that it is impossible to sterilize the mouth, it is fully appreciated that to have it as clean as possible is advisable. So when all is ready, the first step is to thoroughly wash the mouth, teeth, and all the interdental

spaces with an antiseptic solution by means of a compressed-air irrigating machine (not spray), as shown in Fig. 4. Of late, Dakin's solution is being tried

FIG. 4.

An ordinary Hygiea nursing bottle, and stand for same. Rubber stopper held in place by removable clamps. Funnel and valve combined through which the bottle may be quickly filled without removing the stopper. Turning the funnel to the right opens the funnel, and the bottle may be filled; turning it to the left closes it. By turning it more or less, the pressure on the bottle may be regulated. A clip is provided for holding the "tip." The bottle holds eight ounces of solution. It is connected to a compressed-air line in which the pressure has been reduced to five pounds.

out for this purpose, instead of hydronaphthol, which was used in the past. Particular attention is given to, and a great deal of fluid used upon, the tooth

(4) The gum region all about its neck is thoroughly dried by means of napkins, followed by *filtered* compressed air, then painted with equal parts of aconite and iodine, and again dried with filtered air.

(5) By means of a suitable and exceedingly sharp lancet, the gum is carefully dissected from the tooth, care being taken to injure the gum as little as possible. (Fig. 5.)

(6) The greatest care must be used in selecting the forceps, for if the beaks do not fit the root, it may be fractured. None but perfectly smooth-beaked instruments should be used.

USE OF THE FORCEPS.

The writer is particularly fortunate in having a number of forceps specially well adapted to this class of work. Besides the two pairs of the regularly cataloged Kells forceps, designed by his father, as shown on the left side in Fig. 6, he has a number of different sizes and angles, all with smooth beaks made to his own patterns, and from this lot at least one can undoubtedly be found to fit any normal tooth. These were sent out, *soft and in the rough*, from the factory; reshaped and reground by the writer as they were tried on innumerable extracted teeth at the laboratory bench, until they were satisfactory, whereupon they were returned to the factory for the final finishing and tempering.

This work took up many a leisure hour, but the writer was young at the time and rather enjoyed it, and he believes that whatever success he may have had in extracting difficult teeth and roots during all the years which have passed since then is largely due to the adapta-

FIG. 5.

to be replanted and its adjacent neighbors.

(3) The tooth to be operated upon is then carefully isolated by means of napkins.

bility of these instruments to their purposes, for besides the instruments here shown he also has others similarly designed and made for the molars.

According to the writer's ideas, the

forceps and method of gripping the tooth as illustrated in a catalog and shown in Fig. 7, are both radically wrong. The

down, as the case may be, as far as possible. In Fig. 6 are shown typical teeth in the grasp of such forceps. With such

FIG. 6.

The beaks of the forceps are here shown farther up on the roots of the teeth than they would naturally be placed in ordinary extractions, though sometimes, in fact quite often, the beaks act as double inclined planes, and the teeth are popped out with quite a snap, so that from the sound one would think the tooth were broken.

forceps he uses are operated in an entirely different manner. The sharp edges

FIG. 7.

of the beaks are gradually worked up under the gum without injury to it, along the root of the tooth, and pushed up or

well-fitting beaks the danger of crushing weak roots is reduced to a minimum, and all such teeth which have been extracted for the purpose of replanting have invariably been removed without injury.

(7) The tooth is now very carefully extracted, and immediately placed upon a sterile napkin and covered with another.

(8) In the days of old, the socket was never curetted, and yet the abscess invariably healed, but today, immediately upon the extraction of the tooth, the socket is carefully curetted, washed out with warm saline solution with the irrigator (Fig. 3), and then carefully packed with small, sterile, gauze pads. By means of this gentle stream (five to eight pounds air pressure) such a socket can be very thoroughly cleansed without producing any irritation, which result

probably cannot be so satisfactorily accomplished in any other way. Swabbing it out with gauze must necessarily produce a certain amount of trauma. The napkins are now removed from the mouth and the patient dismissed for the time being.

(9) The tooth, being handled in the napkin and never touched by the fingers, is now carefully wrapped with the sterile tape as completely as possible (Fig. 8), and the tape tied on with the sterile floss. In this way the entire portion of the root which will be returned to the socket is protected from accidental contamination during the process of preparation.

FIG. 8.

(10) The tooth is handled in a sterile napkin or by sterile tweezers throughout the operation. Whatever is necessary to place the root-canal in proper condition is now done. If necessary, one or more skiagraphs are taken during the operation. In the end, the root-canal has been cleansed, sterilized, and filled with zinc oxychlorid, possibly gutta-percha points or iridio-platinum wires being used to carry it to place. The end of the root is now cut off *if necessary*, which is not always the case.

If the apical foramen is *small enough*, it is drilled out and threaded for an S. S. W. retaining screw with the instruments furnished for the purpose, and one of these gold or platinum screws is set in, it being first covered with a thin mix of zinc oxyphosphate. If too large for such a screw, the canal is reamed out and filled with gutta-percha. The end of the root and the filling are made perfectly smooth.

The pulp chamber is then filled with oxychlorid of zinc and finished off with whatever material is indicated, when the tooth is ready for replanting. During this part of the work the tooth is securely held by an assistant, giving the operator

the use of both hands, thus expediting the work very materially. Then the patient is returned to the chair, and *if necessary* the region is again anesthetized as before.

(11) The tape is now removed from the tooth, and the tooth is placed in normal salt solution of about body temperature.

(12) The mouth is again well flushed out with the antiseptic lotion. The socket is isolated by napkins, the *surrounding tissue only* is napkin-dried, filtered-air-dried, painted with aconite and iodine, and filtered-air-dried again. *Iodine should never be used in the socket.*

Upon removing the gauze packing, it is necessary to wash out the blood-clot and cleanse the socket thoroughly, which is again accomplished with warm saline solution in the irrigator, and a *little* fresh bleeding, which is desirable, is started.

(13) The tooth is now grasped by sterile tweezers, laid on a sterile napkin, and being handled in the napkin is gently forced to place, and held there securely for about two minutes.

(14) The little blood that usually oozes out at the margins of the gum is wiped away, the splint is set with oxyphosphate in the usual manner, and the operation is complete.

POST-OPERATIVE TREATMENT.

Little or no after-pain results from this operation, and in a few days the sinus, if there was one, is found closed, and the parts are apparently back to normal. During the first week the patient is seen nearly every day if convenient, and the interdental spaces and the necks of the teeth are thoroughly cleansed with the irrigator, and the patient urged to rinse the mouth frequently with the usual mouthwash, or even plain water.

It is usually found that the thickness of the splint, or rather let us say its *thinness*, does not materially interfere with the occlusion, but in some instances a glove-fitting rubber splint has been made to take in the occlusal surfaces of all the teeth in the opposite jaw, and so made as to relieve the replanted tooth of any pos-

sible strain. This to be worn at meals, and possibly at night when "gritting of the teeth" might occur.

The splint is worn for from four to six weeks, at the end of which time the tooth should be quite firm. The margins of the splint are kept well away from the gums, thus leaving the interdental spaces open at the gum line. In one very hopeless case the splint was worn even longer without the tooth becoming sufficiently firm, so the splint was removed, the replanted tooth and a neighboring one were banded, the bands soldered together, and cemented on. This appliance was neither uncomfortable, unsanitary, nor unsightly, and was worn for several months, when the refractory tooth finally did become firm, and so it remains today, nine years after.

THE TIME FACTOR IN CHOOSING THE OPERATIVE PROCEDURE.

It must not be forgotten that oftentimes when there may be no choice between the two operations, the one being just as practical as the other, the question of time involved may be of paramount concern.

The apicoectomist, on the one hand, must spend some time, possibly a great deal, in preparing the root-canals and filling them prior to the operation—if that is his method; or if he amputates the root-end and fills with amalgam first, then considerable time may be spent upon the root-canals afterward. Again, the operator who packs and treats the wound after the operation for a week or more, consumes that many more days. So, taking it all in all, none of these operators can take a case in hand and dispose of it expeditiously.

On the other hand, whatever its previous history, the operation of replanting can be *begun and completed in one day*. Naturally, it is safer to see the patient the following day, but it may not be necessary.

This question of time may be one of great moment to out-of-town patients, and the writer would not hesitate (based entirely upon past experience) to al-

low a patient to leave the city immediately after the operation, consigning him to the care of his local dentist for the watching of the case and re-cementing on of the splint, should it loosen, which it will do sooner or later. When possible, however, he prefers to have the patient remain for several days, merely as a precautionary measure.

MODIFYING THE OPERATION OF REPLANTATION TO CORRECT ALIGNMENT OF TEETH.

Usually, when a tooth requires replanting, it is replaced in its normal socket in the same position it originally held. But very occasionally a case will present when the tooth which needs replanting happens not to be standing in line with its neighbors, and, while one is operating, the socket may as well be changed and the tooth be replanted in the position in which it rightfully belongs, and thus improve upon the original conditions. Under these conditions, several details of the simple replanting operation must be modified to meet the changed conditions. These modifications are as follows:

MAKING THE SPLINT.

Two impressions of the mouth are now taken instead of one, the one to be retained to show the conditions as presenting, the other to be used for making the splint. The tooth to be replanted is carefully cut out of this model, and set in its new position with very thin plaster. From this the usual fusible metal die and modeling compound counter are made: then the counter die is *slightly deepened and enlarged all about the tooth to be replanted*.

The splint is struck up of No. 35 gage (B. & S.) pure gold, and burnished into the enlarged impression in the counter where the metal die would fail to carry it. This should fit all of the teeth snugly except the crown of the replanted tooth. The splint is placed in a small jar of alcohol, and all of the succeeding stages are carried out as already described until we reach No. 7.

CHANGING THE SOCKET.

After the socket has been eurented, it is very carefully cut away in such a manner as to allow the tooth to be replanted in the position desired. This cutting is done with an Ottolengui implantation reamer, which is admirably adapted to this purpose.

After the socket is trimmed, the tooth, being handled in a napkin and never touched with the fingers, is tried in, and if it does not go to place, the socket is again trimmed a little, and this is repeated until the socket is as desired. It is advisable to proceed with this detail very slowly, as unnecessary cutting away of the alveolus is to be avoided.

Again the operation proceeds as before until the time for setting the splint.

SETTING THE SPLINT.

The mouth having been prepared as per step No. 2, the tooth is finally set in place, the splint put in place and carefully burnished to all the teeth and well into the interdental grooves, *except about the replanted tooth*. It is then removed and rinsed and a small quantity of 22-k. solder flowed into all the interdental depressions *near the gum line, keeping it away from the cutting edges*, and again dropped in alcohol. The splint is once again put in place and reburnished, again removed, returned to the alcohol jar, and dried.

A very small quantity of temporary stopping is then spread over the depression which takes in the replanted tooth (this depression was slightly enlarged, it must be remembered), the tip of the tooth is moistened to prevent the adhesion of the temporary stopping, the splint is warmed slightly, and forced to place. The temporary stopping molds itself about the replanted tooth, produces just enough pressure to force it up a little in the socket, and thus overcomes the natural *spring* that such a socket possesses.

The tooth can be held in the exact position desired with a suitable sterile instrument adjusted to its neck (which is not covered by the splint), while the

splint with its softened matrix is adjusted. Allowing a moment or two for this matrix to harden, the splint is removed, dried, and then set *permanently* with cement. The drying of the splint is done by placing it in a sterile gauze napkin, and then the alcohol can be quickly dried out by a few blasts of the filtered compressed air.

Past experience has proved that it is not necessary to replant the tooth the same day that it is extracted, but as a rule this is practicable, and undoubtedly it is better to replace it as soon as possible. One case was met with in which a central incisor was knocked out by a fall and not replaced until four days later, and yet at last accounts, *five years later*, the tooth appeared perfectly normal.

CONCLUSIONS.

Considering carefully the relative advantages and disadvantages of replanting and apicoectomy, the writer concludes that—

(1) The conditions to be found within the root-canals and beyond the root-end must necessarily be and are infinitely better after replanting than after apicoectomy.

(2) That whenever a tooth or root can be extracted without injury to itself, there can be but one choice between the two operations.

ILLUSTRATIVE CASES.

Case I. Upper lateral root carrying a Richmond crown with the conditions clearly shown by the skiagraph, Fig. 9. This undoubtedly would appear to be a typical case for apicoectomy by the fadist, only to have resulted in failure, as the sequence will show.

Upon the showing of this picture, replanting was decided upon, although it was considered a hopeless case, and only undertaken upon the earnest solicitation of the patient.

Upon the extraction of the root (root and crown without injury to either) much of the gutta-percha around the pin was found perfectly loose, and the canal

was in very bad shape, as may well be imagined.

To have done anything at all to such a canal by means of an apicoectomy operation would have been simply impossible, but with the root in the hand it could be and was thoroughly cleaned and filled. The socket was thoroughly curetted, the

ation through the side of the root could be taken care of, which would have been impossible under any other circumstances, so here again is a case where replanting was the only rational procedure possible.

Case III. An upper second bicuspid with a fistula could not be "managed," and it came into the writer's hands for replanting. With the tooth in hand two canals appeared in evidence, and one was still unmanageable, so a bristle was run through the other, the tooth laid upon its side, and skiagraphed as shown in Fig. 11. With this picture as a guide, both canals were expeditiously prepared

FIG. 9.

tooth replanted, and splinted as usual. Recovery was normal, and at the end of six weeks the tooth was perfectly firm, and all conditions appeared perfectly satisfactory, as shown in Fig. 10.

From this picture one would infer that there was but *little left of the root* but the filling, and while this is true to a

FIG. 10.

certain extent, the real conditions are not quite so bad as they appear.

Case II. A lower lateral had been under treatment (the usual kind) for over a month, by the end of which time the patient's patience faded away. Upon examination of the tooth it was discovered that the root had been perforated, and so replanting was decided upon, and the operation was performed according to routine.

With the tooth in the hand, the perfor-

FIG. 11.

and filled, the tooth replanted, and in a few days the fistula was closed, and in due time the tooth resumed its natural duties.

Owing to its *enlarged* and curved end, this tooth was one of the most difficult to extract that had been met with in many a day; the full force of the writer's strength was necessary to get it out. As a result of this, the margin of the labial alveolar plate was slightly fractured, and a few weeks later a small piece exfoliated, but produced no serious consequence, as the tooth is perfectly solid at this writing. Here again is still another instance where apicoectomy would have resulted in complete failure.

Case IV. Fig. 12 happens to be a case operated upon very recently, the patient being a miss of fifteen. The pulp of the upper right lateral was devitalized by

"regulating" when she was nine years of age. The tooth had been abscessed ever since, and presented with a large fistula over the labial surface, and an examination showed considerable destruction of the labial alveolar plate.

The outlook was not encouraging, but an operation was thought worth while. The socket was cut out so as to allow the tooth to be replaced in the arch. Upon completion of the operation the little girl went to a picture show, slept

FIG. 12.

that night as though nothing had happened, and the next day had only the splint to show for it all when she smiled.

Many other cases could be produced to demonstrate that replanting can restore to usefulness many teeth that must otherwise be lost, but these should suffice. It must be understood that there are no claims made as to the methods herein described being the only ones possible for this operation. Other operators may have different ways of accomplishing equally as good results. The aim has been only to describe as briefly as possible the various details as *actually carried out* in the writer's practice.

This paper is written solely for the

purpose of drawing the attention of conservative men of our profession to the advantages of an operation which possibly many of them have overlooked, and if it should perchance serve this purpose the writer will feel well repaid for the time spent upon its preparation.

FIG. 13.

Typical die, and splint made thereon.

An attempt has been made to give a clear and concise description of every step in the operation, so that one who has never replanted a tooth can, if he will, by following these instructions carefully, do so without fear of ill results.

FIG. 14.

Typical glove-fitting splint.

The operation is not difficult. It only requires care and an *absolute* appreciation of the necessity of attention to details. While other methods are possible, this one has proved, by the acid test of time, to be satisfactory.

Dental Engineering and the Normal Arch.

By PERCY NORMAN WILLIAMS, D.D.S., New York, N. Y.

(Read before the Orthodontia staff, Forsyth Dental Infirmary for Children, Boston.
February 11, 1918.)

DENTAL engineering is a term which has been applied so often in describing orthodontic treatment during the past three years that the expression has found a permanent place in dental literature. If we are to accept dental engineering and allow it to become a part of our science, it is well that we clearly understand what it means, and its relation to nature's methods of arch construction. In the first place, all branches of engineering are based upon exact mathematical formulæ, and variations are always considered. Nothing is allowed for variation until the amount of variation has been carefully computed. The finished product must comply absolutely with the predetermined result.

Engineers always assume that if no error has been made in the mathematical calculation, the desired work can be accomplished, and right here we meet the first obstacle in applying engineering methods to orthodontia. In the first place, nature does not grow flowers, animals, human beings, or dental arches to mathematical exactness—the almost infinite number of variations is one of the charming things in nature; but, while not arbitrary, she does follow certain well-defined laws, some of which will be mentioned later.

Another and more serious difficulty in applying engineering methods to orthodontic treatment is that, once we adopt them, we become slaves to a system which is so exacting that it becomes impossible of realization. Dental engineers work under the assumption that teeth can be moved to within one one-thousandth of an inch of some predetermined points, and rest their assumption upon the abil-

ity of the operator to move and place cusps, sulci, and planes in the exact position as shown on the previously laid-out chart. It is unnecessary for me to elaborate upon this fallacy. The old proverb that "Fools rush in where angels fear to tread" can be appropriately applied to the man who knows all about engineering, but little about orthodontic treatment. Such a man gets an idea and allows it to dominate him, distorting his judgment and pushing aside every other consideration to accomplish the purpose.

Most of us who have moved teeth for any length of time know that when we place teeth in positions which approximate occlusion, nature comes to our aid, and by means of dynamics and the inclined planes proceeds to occlude the teeth, and she can do with her methods what man has failed to do since time immemorial. It is fortunate for most of us that this is true, and it is my contention that even if man possessed the ability to place cusps to within $\frac{1}{1000}$ of an inch of the position as indicated on a chart, this is wholly unnecessary.

DESIRABILITY OF A METHOD FOR DETERMINING THE SHAPE OF THE ARCH.

It is of course true that occlusion is largely a mechanical problem, and as such it is closely related to mechanical engineering; but we must always have in mind that a working formula to be of any value must be capable of execution. That there has been and still is a need for some method of predetermining the shape of the arch none of us will dispute.

Ever since orthodontia became a speciality the need for this has been con-

stantly seen, but little has been done to that end. For years the Hawley charts remained the only guide for arch form, and we must concede that they were better than nothing. We have for a long time paid altogether too much attention to designing appliances and perfecting technique without due regard for a great and fundamental problem, that of determining arch form. The ease with which the profession becomes obsessed with a desire to perfect technique was seen some years ago when members of the profession reached such a high degree of skill in manipulating non-cohesive gold foil—some men even going so far as to fill root-canals with this material. It has since been seen that this took precedence over some equally if not more important problems. We emphasize again the need for a flexible working hypothesis for predetermining arch forms, and such a system must be based upon an investigation into the shapes of normal arches as found in nature. Arbitrary laws and mathematical calculations are valuable only in so far as they assist us in determining nature's intentions and faithfully reproducing her works.

Angle, as well as other well-known men in the orthodontic field, has, it seems to me, paid altogether too much attention to the development of appliances, with corresponding neglect of important principles. This is well illustrated in the development of the pin and tube appliance and ribbon arches. Nobody denies that the pin and tube was an attractive, neat appliance, but it is incorrect in principle in a large majority of cases. Any appliance which is attached to the front teeth to make these teeth afford reciprocal anchorage for moving molars distally is not only worthless but actually does harm to the point of creating deformities. It cannot be denied, and we might as well face it as a fact, that there are many examples of the work of prominent orthodontists, as well as of that of general practitioners, which from an artistic as well as an anatomical standpoint are a disgrace to the science, and this in spite of the fact that they may be fair examples of occlusion, but far from normal, because the normal

in anatomy is the very basis of art, and therefore could never cause disfigurement.

I do not wish to be misunderstood here. I of course firmly believe that normal occlusion is the very basis of dentistry, but we have no moral right to point with pride to the fact that we have brought teeth into some kind of an occlusion based upon our own personal opinion, and assume that the anatomical form of the arch is correct. The common practice of first selecting the appliance or the system, and then being limited and becoming slaves to the narrow sphere of this particular appliance, is not only illogical but absurd. It would be better to have a clean-cut, definite idea of what is to be done in a given case, and then select the appliance best suited to accomplish the desired movement.

This principle of using the anterior teeth as anchorage for moving molars and creating space for cuspids as a common practice was strongly impressed upon me recently, when a woman called to consult me regarding orthodontic treatment for her daughter of twelve years. About the first question she asked was, "Is this work going to change the child's mouth?" I assured her that a normal arrangement of the teeth would improve the girl's appearance, but she seemed very much concerned lest the child's mouth should be made larger. She then informed me that she had known several children whose teeth had been straightened and the results, to use her own words, "were hideous," and if it were going to change her child's mouth to the degree that she had seen in others, she guessed she would not have the work done. I tried to assure her that the very basis of art was normal anatomy, and that what she had seen was not the normal. This is a serious matter, and one which cannot be lightly brushed aside. Is it not about time to get down to a scientific basis for the arrangement of teeth and eliminate this stigma from the profession? This moving of the anterior teeth forward to create room for cuspids is not confined to any one school or to the followers of any particular system, nor is it due to any particular kind of

appliance, but to a lack of any definite plan of action and of a comprehensive idea of the positions the teeth should occupy in a normal arch. Whether it be a fact or not that teeth can be occluded in one arrangement only, certain it is that there are arches that are characteristic of the operators who shape them. There is a certain orthodontist whose patients' arches I could recognize if I excavated them from the earth twenty years from now. The teeth are so carefully arranged after his own distorted mental image of what the normal arch really is, that there would be no mistaking them.

IMPORTANCE OF DIAGNOSIS OF CAUSES BEFORE ATTEMPTING TREATMENT OF MALOCCLUSION.

I wish this to be taken in the spirit in which it is intended, *i.e.* that of constructive criticism. If I speak frankly it is because I feel that these facts have long been known but rarely discussed, and the time has arrived when we should deal with this question with a critical, analytical mind. Most of us who have been practicing orthodontia for any length of time know that there are many cases where the results have been disappointing. Therefore we should meet on common ground when it comes to the question of inquiring into the causes of these unfavorable results, and look for a remedy. The first step toward this is careful, painstaking diagnosis, and such a diagnosis does not end when we consider the relation of the lower teeth to the upper; be this done never so thoroughly, there still remains the relation of the teeth to each other within each jaw. In quite a percentage of cases we find that the upper first molars are not equidistant from the median line. This means that one molar has migrated toward the median line, probably due to the premature loss of some tooth on the affected side.

It must be borne in mind that a first permanent molar drifts forward with remarkable ease when unobstructed, and unless some method or system is devised for determining the correct position of

this malposed tooth, the arch can never be symmetrical nor the teeth occupy normal positions. Frequently there is premature loss of a deciduous cuspid and a subsequent drifting forward of the teeth on this side, so that when the permanent cuspid erupts there is a collapsed condition in the region, with no room for the cuspid. A careful examination here, to determine what teeth have drifted to cause this crowded condition, would enable the operator to intelligently correct the trouble and place the teeth where they belong, that is, in their normal positions. Unless he first determines what teeth are out of position, it is highly probable that he will move the wrong teeth in trying to create room for a malposed cuspid. This is one of the chief causes of the unhappy results we see in children who have undergone orthodontic treatment.

We have reached a point where it becomes necessary to break down certain traditional beliefs which have been obstacles in the path of orthodontic progress for a long time. In Angle's latest edition, under treatment of class I cases he says, "The malposed teeth are usually confined, however, to those anterior to the molars, and more commonly to the incisors." In further describing treatment of this class he says, "Not until the incisors had been moved labially sufficiently for the full admission of the cuspids into the line of occlusion was any effort made toward elevating them." Again he says, in describing class I cases, ". . . the distinguishing characteristics of the class being the relative normal relations of the jaws and molars in correct relation mesio-distally, although one or more may be in buccal or lingual occlusion. The arches are diminished in size, and the teeth, especially the incisors, occupy positions lingual to normal."

I have carefully re-read several times the chapters from which I have here quoted, and I believe it to be the intent of the author that where there is occlusion of the first permanent molars, neither the upper nor the lower first permanent molar is to be moved distally.

If this be so, we have here one of the most fundamental errors which has ever been promulgated in dentistry. I shall be able to prove to your satisfaction, I hope, that in a large number of cases under class I it is necessary, in order to obtain symmetry and a normally shaped arch, to move distally the upper first permanent molar on at least one side, and often on both sides. This is especially true in cases where there is a collapsed area in the cuspid region.

Angle says, in describing a case of class I, "... the result of the premature loss of the right upper deciduous canine which has disturbed the normal process of development of the denture. The upper incisors on the right side have been forced by the lip to occupy positions lingual to the line of occlusion, thereby compelling the right permanent canine, upon its eruption, to occupy a position of much labial prominence, but as the jaws and the molars are normal as to their mesio-distal relations, the case is easily diagnosed as belonging to this great class." Angle probably bases his assumption that the incisors must be moved forward to make room for a prominent cuspid upon a law which he has formulated, and because at the time he wrote the latest edition of his book the Baker anchorage had rarely been used except to move teeth in class II.

ANGLE'S LAW FOR OBTAINING HARMONY OF FEATURES THROUGH TOOTH MOVEMENT.

Angle's law for obtaining harmony of features through tooth movement reads as follows:

Now, the ability to determine the proper balance of the features is rare. One of our foremost teachers of art, Mr. E. H. Wuerpel, says that only one in two or three hundred of even art students ever succeed in mastering it, and these only after much observation and practice in sketching and modeling the human face. Yet, discouraging as even this seems, we believe there is a law for determining the best balance of the features, or at least the best balance of the mouth with the rest of the features, which artists probably know nothing of, and one which for our

work is far more unvarying and more reliable than even the judgment of the favored few. It is, furthermore, a law so plain and so simple that all can understand and apply it. It is that the best balance, the best harmony, the best proportions of the mouth in its relations to the other features, require that there shall be the full complement of teeth, and that each tooth shall be made to occupy its normal position—normal occlusion. This law may be regarded as one of the cornerstones of the new school of orthodontia in contradistinction to the teaching that has always dominated the practice of the old school, that of leaving to the individual judgment of the operator, without any standard or law, the determination of the requirements in orthodontic operations in each given case.

Angle has stated a law here which is fundamental and unshakable, but its application is not a part of it, as he would have us believe. In fact, its practical application is just the question that we now consider paramount, namely, placing all the teeth in their anatomical positions. Angle considers the application of this law a simple matter, because he bases it upon the false assumption that if the first molars are in occlusion they are normal mesio-distally. Turning to other authorities, we find Case flatly contradicting this law of Angle's, and stating that in order to obtain harmony of features and beauty of form and expression the full complement of teeth is not necessary, and therefore in certain cases he advises extraction. It is very clear to one who reads the works of these men carefully that each of them is trying to state a law which will be universal in its application and obviate the necessity of individual judgment. We find a conflict of opinion here, and have no hesitation in stating that neither has offered a solution. These men, along with other authorities, have, it seems to me, tried to inculcate laws or principles that could be universally applied for producing artistic results, but which laws are without a scientific basis.

A study of normal anatomy is the very foundation of art as related to human form, yet there is no evidence that any of these writers have made even a superficial investigation to determine shapes of normal arches, their variation, and

the relation of arch form to facial contour. The profession has been misled

results follow. *This is true only where the teeth occupy normal positions in re-*

FIG. 1.

(Drawings by J. Earl Schrack.)

for years by the fundamental error that if teeth are moved into occlusion, artistic

lation to the rest of the skull, and we cannot move the upper teeth anywhere we see fit in order to obtain occlusion,

and expect artistic results to follow. The relation of the teeth to the skull is just as important as is their relation to each other. It is of deep concern to the parent of a child if in obtaining occlusion we produce deformity.

Let me quote here from Lischer:

The duties of the orthodontist force upon him great responsibilities, and there is nothing in which the student of orthodontia should be more keenly interested nor better informed than in the study of the artistic proportions and relations of the features of the human face: for each of his efforts, whether he realizes it or not, makes for beauty or ugliness, for harmony or inharmony, for perfection or deformity. Furthermore, besides forming an important phase of the difficult art of diagnosis, it involves us in "the most remarkable problem of esthetics," viz. that of beauty of form. Ignorance of these requirements has led numerous operators into the unenviable position of having permanently marred the beauty of an otherwise handsome face.

ARCH FORM DETERMINED BY THE SHAPE AND SIZE OF THE TEETH.

The artist, in painting a portrait, reproduces on canvas the individual as he sees him: that is, he attempts to portray a personal likeness which will reflect character. The orthodontist is not rendering treatment primarily to obtain artistic results, nor is he arranging teeth to produce correct facial outline. These are incidental and but a secondary consideration to the all-important subject, correct anatomical arch form and normal arrangement of the teeth. It logically follows, then, that it is impossible for the operator to render orthodontic treatment and hope to obtain satisfactory results, when such a course of treatment is based upon his own individual judgment. Any opinion which rests upon his conception of what is artistic is absolutely precluded, also he is decidedly limited in the arrangement of the teeth. He is not free to shape the arch according to principles in art or to his own personal taste, because the shape and size of the teeth have already determined this, which completely eliminates individual judgment.

The relation of the teeth to the jaw is much the same as that of the fingers to the hand. I have discussed the question with several recognized authorities on portrait painting. It is the opinion among all of these men that the shapes and sizes of the fingers determine the shape and size of the hand: that is, with

FIG. 5.

long tapering fingers we would have a long slender hand, and with broad, short fingers we would have a broad, short hand. Applying this principle to the teeth, we would expect with short broad teeth to have a broad jaw, and if the teeth harmonize with other physical characteristics, the individual would have a full round face. On the other hand, long narrow teeth would make a narrow jaw,

which would be found in a person with a long narrow face. I have had an artist draw some sketches of hands from life, and from these make some drawings of abnormal hands which illustrate my point. (See Figs. 1 to 4.)

The amount of variation within a given type is extremely small. The variation is almost wholly dependent upon variations in the size of the teeth. The mesio-distal diameters determine the width of the arch, that is, there is a con-

FIG. 6.

Drawing from life, with the anterior teeth arranged to a circle approximately normal for this sized arch. The laterals and cuspids appear narrow, due to foreshortening.

FIG. 7.

Same teeth as in Fig. 6, with abnormally large circle for the anterior teeth. Here the cuspids appear larger, because of the lack of foreshortening.

In an article entitled "Determining the Shape of the Normal Arch," published in the DENTAL COSMOS for July 1917, I submitted measurements and other data to substantiate my claims for the shape of the normal arch for the American type. I wish it clearly under-

stant ratio between the diameter of the teeth mesio-distally and the distance between the first permanent molars. This enables us to determine what the width between the molars shall be. Once we get this we are able to find the radius for the front teeth, and with the aid of

FIG. 8.

Extremes in variation from given sized teeth. Ratio 14:9 maintained throughout.

stood that I am not discussing any other type, and the variations I shall show are confined strictly to this class of individuals. When I say the American type, I refer to those descendants of the Pilgrim Fathers who are characterized by high cheek bones, firm jaws, and rather angular features. I have selected an individual who well represents this type (Fig. 5.)

a small measuring instrument we can lay out the line for the bicuspid.

I believe it to be a fundamental law, not only in man but throughout the animal kingdom, that the shape and size of the teeth determine the shape and size of the jaw. I am supported in this contention by Dr. Clark Wissler, director of the department of anthropology of the Museum of Natural History of New

York, who expresses the following opinion: "There is no anatomical part in mammals so uniform as dentition. Even between primitives and man there is a striking likeness in the shape of the jaw. Teeth make the arch, and the species variability is so small in a racial type that it requires careful measuring to detect the difference in shape."

It is stated upon reliable authority that Agassiz could take a single bone of an extinct species and reconstruct the entire animal, but he based his ability to do this upon an intimate knowledge of comparative anatomy, and it was always an average type, not one showing marked variation from the normal. The hypothesis which I submit to you is essential before normal variations can be determined, but the important lines of the arch must always remain the same in any variation. That is the 14:9 ratio. The three normal variations are shown in Fig. 8. It is impossible to have a correctly shaped arch without first constructing the average for a given size set of teeth; from this variations can then be made.

CONCLUSIONS.

(1) Dental engineering is an unfortunate term to use in describing methods

of determining arch form. It imposes upon the profession strict mathematical formulæ impossible to follow, and contrary to nature's laws.

(2) Occlusion is a mechanical problem, and dynamics control the positions of the teeth. As we approach correct arch form and normal occlusion, nature, by means of the inclined planes, finishes the operation.

(3) Progress in orthodontia has been retarded by emphasizing methods and appliances and neglecting important principles and laws.

(4) Artistic results follow correct anatomical form. This eliminates individual judgment. Many arches are deformed and mutilated because judgment in art has been left to the individual.

(5) Because of incomplete diagnosis, many operators move the wrong teeth to obtain correct arch form.

(6) Normal occlusion produces artistic results only when the teeth are in normal relation to the skull.

(7) Teeth make the arch, as fingers make the hand, and arch variation is very slight except when teeth vary in size and shape.

40 EAST 41ST ST.

Asepsis vs. Antisepsis in Root-canal Procedure.

By DAVID WIELD McLEAN, D.D.S., Mount Vernon, N. Y.

(Read before the union meeting of the Fifth District and Jefferson County Dental Societies, held at Watertown, N. Y., December 14 and 15, 1917.)

AN Y comprehensive consideration of root-canal procedure today should include three aspects, the economic, the mechanical, and the surgical. It has long been considered bad taste to discuss economics in a scientific paper, but I am firmly convinced that one of the reasons for the worldwide prevalence of wretched root-canal work is the deep-seated conviction many of us have that the patient is not willing to pay for anything else.

- Let us suppose, for the sake of argument, that some man came to this meeting leaving a practice in which it was his custom to half devitalize the pulp and to half fill the root-canals with mummifying paste. Let us suppose this man goes home determined that he will fill every root-canal to the end. He will go back to a practice 60 per cent. larger than the one he left. I mean by that, if he takes care of the same number of patients and does his root-canal work as perfectly as is humanly possible, he will have to spend 60 per cent. more time in his office.

Where he could under the old *régime* devitalize a pulp and fill a canal in three-quarters of an hour, it may now take him three, four, or five hours, and sometimes more. The question arises immediately, Is the patient willing to pay for this, or must the dentist give the case this additional time without remuneration? If we say that he should do the work as suggested without additional remuneration, he will very likely go home and continue to do very much the same kind of thing he has been doing. His conscience may trouble him some, and

he may lose some of his self-respect, but the important economic fact remains that he must earn a living; his family must have food to eat and clothes to wear, and his children must be educated.

Those employed in a philanthropic organization may fill root-canals to the end without remuneration because such an institution is endowed, but unfortunately the average dentist is not endowed, and however much we dislike a discussion of business matters in our professional relations, the fact remains that we shall never be able to put our ideals into practice until we consider well the business aspect.

The remuneration for root-canal work should be on the same basis for time required as is the remuneration for amalgam or gold work. And it is a great mistake to think for a moment that the patient is not willing to have it so.

The patient who questions a fee of ten, fifteen, twenty dollars or more for a root-canal operation will be willing to pay fifty dollars for an automobile tire, for the simple reason that he knows the service the tire is going to give him, and thinks it worth the price. The conclusion is very obvious. We must educate our patients to the importance of correct root-canal procedure. Explain to them the things we now know about focal infections and their systemic sequelæ. Do not frighten them, but let them know in a casual way that myositis, arthritis, endocarditis, kidney lesions, gall-stones, neurasthenia, neuritis, eye disturbances, skin disturbances, boils, etc., may follow in time from faulty root-canal procedure. Explain to them the possible dangers

from the so-called blind abscess, and also explain what immunity means. Point out that in a great majority of cases the patient's immunity wards off these ills, but if for some reason his resistance to infections is lowered, these things may follow.

Impress upon them the fact that for these reasons a great responsibility rests upon the dentist when he is engaged in root-canal work; that it is no longer possible for a conscientious dentist to partially devitalize pulps and half fill root-canals; that this work now requires a great deal more time than it once did, but that it is well worth it, and may be considered as health insurance. You will notice that I have not mentioned fees—it is not necessary. The patient already has some idea of your fees in general, and has probably figured that out for himself, and arrived at a fairly accurate idea of what they average per hour. Just let the patient understand that his welfare demands several hours of your time instead of one, and he will not only want it, but will insist on having it.

Just as soon as we can drive home to the rank and file of our profession the fact that painstaking and reasonably perfect root-canal work can be done, and that the patient can be educated to a proper appreciation of it; just so soon as we can drive home the fact that the X-ray machine will far more than pay for itself by facilitating our operations, just that soon shall we see the rank and file of our profession doing really good canal work, and checking up every filling with a radiograph. The day is coming—and we may look forward to it as the dental millennium—when there will be an X-ray machine in every dental office in which there is a dental engine, and the improved root-canal work resulting from its use will be the greatest boon conferred on humanity in several generations.

PULP DEVITALIZATION.

Inevitably linked with the question of root-canal procedure is the consideration of pulp devitalization. During the past two or three years many of us have

quaked at the thought of devitalizing a pulp, and I fancy that thousands of pulps have been capped which should not have been left vital. Rosenow and Price have established beyond question the fact that infection may be found in a vital and even an unexposed pulp, and it is perfectly logical that this should be true.

We know that infection is migratory; that if we have a nidus of infection at any point of the body the bacteria developed in that nidus will be carried by the circulation and lymphatics to every part of the body, and that wherever they find a tissue whose resistance has been impaired they will stop there, and make that their point of incubation. When a pulp once becomes inflamed or exposed and has to be capped, there is not only the chance of the introduction of infection from the mouth or instruments, but there are circulatory changes in that pulp which result in a lowering of its resistance, and it may readily become a focus of infection, secondary to one somewhere else in the system.

Dr. Leuman M. Waugh of New York City has for several years claimed that it is better to devitalize a healthy pulp than to wait until it has undergone putrefactive degeneration; and the latest research in this direction certainly substantiates his claim.

Two hours after writing the preceding paragraphs, the writer was asked to help a new patient who was suffering considerably. There was neuralgic pain throughout the left side of the face, and a great deal of soreness in the region of the submaxillary lymphatic gland, the neuralgia of course indicating a congested vital pulp, and the inflammation in the gland a focus of infection. We suspected an upper molar, which had a temporary filling in it, of being the tooth with a congested pulp, and a lower molar which had a large silicate filling in it and appeared to be dead, of containing the focus of infection. Investigation, however, showed that the cavity in the upper molar was very shallow, and did not enter into the question; under the large silicate filling in the lower tooth (and

it was a very deep one) we found a vital and congested pulp.

Here was a case where there was sufficient infection in a vital pulp to affect the lymphatic gland controlling that region. How much better had it been if the operator who put in the silicate filling had first devitalized the tooth!—he would have had a sterile field in which to operate. Therefore if our good judgment dictates that a pulp should be devitalized, we must have the bravery to devitalize, and the courage to do it properly.

Now, just as lowered resistance will predispose to infection in a vital pulp, so the lowering of resistance in the periapical tissues will do the same thing, and there is food for serious thought in this fact.

USE OF DEVITALIZING PASTES.

Arsenic is one of the most penetrating tissue poisons, and should be used with great discrimination, if at all. There can be no doubt that the periapical tissues are often destroyed by the arsenical treatment. As far as the tooth is concerned, conduction anesthesia is the ideal plan for pulp extirpation. It is not always possible to apply pressure anesthesia, especially where the pulp is not exposed. Sometimes an application of Buckley paste or "velvo-phenox" (a similar and very satisfactory preparation which antedates the Buckley paste by a couple of years) will enable one to expose the pulp, after which pressure anesthesia may be used. However, there is always danger of forcing infection into the periapical tissues by this method of treatment.

When it is necessary to use a devitalizing fiber of the arsenic type, the writer prefers that manufactured by the Velvo Co. It contains so little arsenic, and that little is so well locked in chemical combination, that it can be sealed in the cavity with simple cotton and sandarac—in fact it is more effective when sealed in that way. A trying situation arises when the apical ends of pulps are not devitalized by the arsenical treatment.

In these cases it is not safe to again

use arsenic; pressure anesthesia may force some trace of arsenic through the foramen, and other agents, such as silver nitrate or trichloroacetic acid, are hopelessly inefficient. In these cases the writer uses the Buckley desensitizing paste or "velvo-phenox," of which a small quantity is placed in the canal with a broach, a piece of cotton moistened with formocresol is placed over it, and it is sealed with gutta-percha for about a week. There will be no pain, and seldom any pericementitis. This is the most efficient agent I have found in these cases. The treatment may be repeated if necessary.

Last spring, in a paper read before the New Hampshire State Dental Society, I stated that with the radiograph I had found lesions following this method of treatment. A study of further data reveals the fact that an abnormally large amount of filling material was forced into the periapical tissues in some cases—but the percentage was about one-half of 1 per cent., and this result may have been due to large foramina or less dense peridental membrane than normal. If we are going to fill our canals to the outer edge of the apical foramina we are going to "encapsulate" a certain percentage of root apices; it simply cannot be avoided.

Time may prove the use of formaldehyde-liberating preparations in this connection to be unwise, but the indications in that direction at present seem practically *nil*.

ROOT-CANAL INSTRUMENTATION.

The first requisite for canal instrumentation is accessibility. Do not ream root-canals through pinhole cavities; do not drill small openings through large fillings or gold crowns—remove them. Do not treat anterior teeth through small lingual openings at the cervical margins; make an opening approximating the size of the pulp chamber, so that it will not be left full of putrefying pulp tissue to discolor the tooth and infect the canal filling. If there is a curve in a canal, cut away the tooth structure in

such a way as to straighten it out. If there is a corner or wall in the way, cut it down. Remember always that the vital thing is to get a perfect canal filling; after that it will be time enough to worry as to what you will do with what is left of the tooth.

To get to the apex of a virgin root-canal is not as a rule very difficult. The trouble very often is that we start wrongly, and mar the canal. If we start the canal with a Gates-Glidden drill or a stiff reamer, the chances are that we may cut a niche somewhere in its walls, after which reaming becomes exceedingly difficult.

When the chamber is wide open and all overhanging structure removed, isolate the tooth and dry the chamber well. Then hold the electric mouth lamp, having unclamped the mirror from it, close to the cavity, at such an angle that you can see the whole interior of the chamber. Never *feel* for root-canal openings—*see* them. Now give the mouth lamp to your assistant to hold while a fine antalum or fine long-handled Young broach is worked into the canals—do this no matter how large they look—exploring them carefully to locate any curves that may be present. If these instruments will not enter readily to the approximate length of the canals, use the smallest size Young broach, short handle, and ream the canal very gently. When this broach has reached the apex use the next size; then enlarge the orifices of the canals for about one-eighth of an inch into the canal with the three sizes of Gates-Glidden drills; then use larger broaches of the Young or Kerr type, always remembering that larger sizes break more readily than the smaller ones.

In the treatment of blind abscesses, we find our most difficult instrumentation. A great many of these canals are almost entirely obliterated by very dense secondary dentin.

The Callahan sulfuric acid solution (30 to 50 per cent.) is a useful aid in opening such canals. First dry the canal with Johnson & Johnson absorbent root-canal points and compressed air. Apply the acid with antalum-beaked col-

lege pliers, or on a wisp of cotton as advised by Callahan, pumping it up with an antalum broach, and after *one* minute follow the sulfuric acid solution with bicarbonate of soda, saturated solution, pumping this up also.

A useful treatment for dressing very offensive putrescent canals or canals into which pus drains is a combination which the writer calls "phenol-iodid." It is a saturated solution of iodine crystals in pure phenol. It contains an extremely high percentage of iodine, and should be discontinued as soon as suppuration ceases, which will be after one or two treatments. I like to use this on a wisp of cotton in the canals, and a large pledget of cotton saturated with formocresol in the pulp chamber, sealing the tooth with gutta-percha. The formocresol aids by liberating formaldehyd gas. After suppuration has ceased, formocresol is used for perhaps three or four dressings, leaving them *in situ* for four or five days at first, and later lengthening the period to ten days.

ROOT-CANAL FILLING MATERIALS.

Let us now for a moment consider the subject of root-canal filling materials from a purely mechanical point of view. One requirement common to all materials is that they must be introduced into a dry canal. First dry the cavity, then the canal, with Johnson & Johnson points, place a small quantity of 70 per cent. alcohol in the chamber, and pump it into the canals. Then dry again with Johnson & Johnson points and hot air. The writer finds himself using the root-canal dryer less and less, for the reason that it must either be applied hot enough to cauterize, or else for a period of several minutes; it also is apt to go through the foramen in many cases and cause hemorrhage. When you think the canal is dry, go back to the Johnson & Johnson point as a test; if the apical tip of the point comes out dry, the canal is ready to fill. Remember that neither chloro-percha nor medicated paste (which usually is an oil) can be pumped into a moist canal.

From a purely mechanical standpoint

the writer objects to gutta-percha or chloro-percha for two reasons: (1) It shrinks on hardening, as has been proved by the experiments of Weston A. Price and by numerous radiographs; and (2) because it is not sufficiently adhesive to seal the canal. Recently the writer removed a gutta-percha filling which had been introduced two weeks before into a dry cavity previously moistened with eucalyptol, which will make gutta-percha adhere to almost anything. The patient chewed tobacco. The outer surface of the filling when removed was white and clean, but the entire inner surface was stained a bright yellow by tobacco. The addition of the rosin-chloroform solution (Callahan) will make the material more adhesive.

A good plan is to use first the rosin solution, then chloro-percha, then gutta-percha points. The two solutions are pumped to the apex with a broach. This combination shows much better in radiographs than the rosin solution and points alone. The greatest objection to gutta-percha is that it is non-germicide, and absorbent; it absorbs serum, etc., and becomes very offensive.

THE AUTHOR'S TECHNIQUE FOR FILLING ROOT-CANALS.

With your permission I shall now describe my own pet root-canal filling technique.

The material I use is a medicated paste or, more correctly, a paste made up entirely of medicines, the formula of which is: Bismuth subnitrate (a white powder) four parts, iodoform one part; mix on a slab or in a mortar and add formocresol q.s. to make a paste.

This paste is placed in a glass-stoppered bottle with a wide neck. After a week or so it will dry out somewhat. Each mix is spatulated for a moment with a drop of formocresol before using. The proper consistence is that of a cream, just thick enough so that it will not run into a ball when taken up on the broach.

The canal having been dried, a very small amount of the paste is taken upon

the smallest size antalum broach, which is very flexible and yet fairly stiff. The paste is carefully carried down one side of the canal and pumped at the apex until the patient feels it, or the tooth begins to ache slightly. This grumbling pain is caused by the formocresol, and will last from three to ten minutes. The writer has used formocresol in this way for seven years, with uniformly good results. There is very little or no pericementitis following the filling of the canal. Care should be taken not to trap air under the filling material. When removing the broach from the canal, keep up the pumping motion until the broach is all the way out of the canal. If the instrument is withdrawn in a single motion, it may draw the material away from the apex.

The entire canal is filled with paste, and the chamber filled with gutta-percha, and packed over each canal with small and large pluggers.

If a porcelain crown with a post is to be used, I first fill the apex with bismuth-formocresol paste as described above, pump in chloro-percha, and then pack in small-sized Canfield gutta-percha points (unheated) with Ivory curved root-canal pluggers, until the canal is about one-third filled. The filling is of course radiographed before the crown is set. This paste and chloro-percha unite nicely, and whenever the writer uses chloro-percha and gutta-percha, he starts with bismuth-formocresol paste at the apex.

This paste shows up well in radiographs; this is essential in any material, for no matter what material or method we use, we shall have to refill a goodly number, and some two or three times, before the perfect filling is achieved.

ASEPTIC AND ANTISEPTIC OPERATIONS.

The final phase of our operation is that which lifts it out of the realm of the purely mechanical into that of surgery, namely, the control and prevention of infection.

There are two forms of surgical pro-

cedure. One requires that micro-organisms shall positively be kept out of the field of operation, and is known as asepsis; the other eliminates by irrigation and sterilization any bacteria in the field, and is known as antiseptis. One cannot operate on a suppurating field or under conditions such as may be found immediately behind the line of battle, by purely aseptic procedure. Hence we have, for example, the Carrel-Dakin method of treatment of wounds so much used in the surgery of the present war, which is a conspicuous example of surgical antiseptis.

In root-canal procedure we have two schools of thought, two methods of procedure, which we might correctly call those of asepsis and antiseptis.

The advocate of the use of gutta-percha is usually also an advocate of asepsis. He will tell you that if every step of the operation is performed under *absolutely* aseptic conditions, no drugs will be required, and a neutral material like gutta-percha will, if sterile itself, fulfil every need. I believe this to be true except for the one important fact that gutta-percha is absorbent and soon becomes very offensive. I also believe that it is not reasonably possible to perform an *absolutely* aseptic operation in the mouth. What would constitute such an operation?

Let us apply to a root-canal operation the requirements upon which a surgeon would insist in performing a laparotomy. First we must have an operating room with tile floor and tile or painted walls and ceiling. There must be no carpet or rugs, no wall paper, no pictures on the wall, no furniture except such as can be washed, and no plush or leather or cloth covers on the operating chair. There must be no cotton or other waste thrown on the floor.

The entire outfit, room and furniture, must be thoroughly washed frequently, and no one must come into the room in street clothing. The operator and assistants must have a dressing-room, and change all outer clothing. The patient must be taken to a dressing-room and his clothing changed for hospital attire.

Before entering the operating room the mouth and face must be cleansed with germicidal solutions. A turban of gauze must be wrapped about the hair to prevent a shower of germs upon the field of operation. A mask should then be fastened over the patient's nose for the same reason, and the rubber dam applied so as to cover the entire face, for the operator's fingers must not touch the patient's skin. The dam and cavity should be washed with iothion or iodine, and the patient is ready.

Meanwhile, the operator and one assistant have donned caps and masks and rubber gloves, in addition to their operating clothing, and have sterilized their gloves and arms. *There must also be an unsterile assistant*, for a radiograph may have to be held up for inspection, or a window closed, etc., *and the operator and sterile assistant must not touch anything unsterile.*

Of course it goes without saying that the instruments, cotton, gauze, napkins, cotton points, gutta-percha points, chloro-percha, and everything else used during the operation, have been thoroughly sterilized.

Now, if a surgeon performs an appendectomy under these conditions—and he would insist upon every one of them—and finds that he cannot remove all of the infected tissues, he resorts to drainage, irrigation, and dressings. In other words, he brings into his procedure antiseptis.

Do you think that if the surgeon were filling, even under these conditions, a root-canal which had been attended by periapical infection which he could not reach with knife or curet, he would be willing to discard drugs, and crowd into that canal a non-germicidal and porous material like gutta-percha?

But, someone may say, that only applies to cases of apical infection. Granted; but has it not been shown that exposed or even congested pulps may contain and probably usually *do* contain infection? And how many pulps do we remove which are not either exposed or affected by pulpitis?

But aside from that, and granting that

gutta-percha may be correctly used with this strictly aseptic procedure, do you think it would be feasible to perform dental operations under this strict definition of absolute asepsis? What would be the cost of a filling which required entering the canal three times?

Now, what constitutes antiseptis in root-canal procedure? There is a prevalent idea that it means careless procedure; that it disregards all aseptic precautions, and depends entirely on a dab or two of phenol or creasote.

May I take just a moment more in which to sketch a correct operation under antiseptis?

The dam should be applied or the tooth isolated with cotton rolls. The canals should be reamed to satisfaction. Dressings of formocresol should be sealed in the canal until there is reasonable assurance that the infection is cleared up. If the case is complicated by any manifestation of secondary infections, a culture should be taken to establish the sterility of the apical area.

The canal is then irrigated well with water, and fresh cotton rolls or dam ap-

plied, and the canal dried thoroughly and sterilized by pumping into it phenol-sulfonic acid with an antalum broach. Bicarbonate of soda solution is then pumped into the canal, and if cotton rolls are being used, the cavity is packed tightly with cotton and the patient allowed to rinse the mouth.

Cotton rolls are reapplied, and 70 per cent. alcohol applied in the canals to dehydrate them; they are dried with absorbent points and hot air, and filled, as before described, with bismuth-formocresol paste, which is itself positively germicidal. Not only is any infection present in the canal destroyed, but we are bringing to the periapical tissues bismuth, a germicide; iodoform, a germicide; tricrosol, vastly more efficient as a germicide than phenol; and a sufficient quantity of formaldehyd gas will be liberated to aid in sterilization, and to produce a stimulating effect on the surrounding tissues.

These are the two methods of procedure; it is for each operator to choose for himself.

125 PROSPECT AVE.

Standardization of Root-canal Work.

By MILTON J. WAAS, D.D.S., Camden, N. J.

(Read before the Pennsylvania Association of Dental Surgeons, of Philadelphia.
February 12, 1918.)

THE trend of all modern thought and work is toward standardization. It might also be said that as we approach standardization, we approach efficiency. This is also true in dentistry. Amalgams have been largely standardized, casting technique and cavity preparation being likewise examples of where we have emerged from confusion on to safe ground.

In no branch of operative work, however, is there greater interest or greater confusion at the present time than in root-canal work. It will therefore be my endeavor tonight to present this subject in such a manner that we may come to an understanding of what we really desire in our root-canal operations. This I believe to be of fundamental importance. After we once agree upon the necessities in root-canal work, we may build upon a solid foundation, step by step, the best method or technique to accomplish these. The requirements of root-canal work, I believe, fall under ten divisions, and I shall consider the subject under these ten divisions separately.

I. ASEPSIS.

We must use all possible aseptic precautions in all cases. Before such a society as this, it is not at all necessary to enter into a discussion of the desirability of this first requirement, or to go into a detailed description of the methods used in performing aseptic operations. Only a brief reference to this feature of the operation will therefore be made. The proper care of the mouth by spraying and painting the mucous areas

encroached upon by our clamps, etc., should be constantly kept in mind, as well as the proper care of the rubber dam before and after application and the use of sterilized instruments, particularly broaches of any description. These aseptic precautions must also include the ultimate sterility of the canal and all filling materials to be introduced therein.

II. ANTISEPTIC PRECAUTIONS IN TREATING PUTRESCENT CANALS.

We must use in addition antiseptic and mechanical precautions in all previously putrescent or infected pulp conditions. That we should add antiseptic precautions to the usual aseptic precautions in all previously putrescent or infected pulp conditions in order to render the contents of the root-canal innocuous as they are removed is equally as obvious as the first requirement. By mechanical precautions I mean that care should be used during instrumentation not to force any of the canal contents through the apex of the root into the apical region.

III. OBTAINING FREE ACCESS TO THE CANAL.

We must obtain the necessary direct access to all canals at any sacrifice to the crown of the tooth. For this purpose radical sacrifice of the crown portion of a tooth is the height of conservation. We cannot perform perfect root-canal operations without direct access to the canal, and any false saving of the crown portion spells ultimate entire loss of both crown and root.

IV. THOROUGH CLEANSING OF THE CANAL.

We must remove all root-canal contents. If for any reason it becomes necessary to remove the dental pulp, we must remove it completely. Incomplete removal, whether due merely to careless work or based upon any method such as the Herbst method or pulp mummification or the recently advocated silver deposit method means, in the long run, only a gamble with the patient's vital resistance. If I were to hand any member of this association a tooth and ask him the accurate length of that tooth, he would probably take a pair of calipers and place one pointer on the root-apex and the other at the farthest extremity of the crown enamel. If this same tooth should be rendered transparent by the method of Adloff and Krause, or a vertical section made through the center, and I asked the length of the pulp of that tooth, he would probably keep the one pointer as first placed at the apex and close the other until it just touched the lowest extremity of the pulp chamber. This would represent its length, and this much we must cleanse thoroughly. That is, we must remove the contents to the outside of the apex. This is where the organic matter enters the root, and this is the point to which we must work; to fall short of this is to do incomplete work. The idea that we must work through the apical opening to its outside extremity is the discovery of Dr. M. L. Rhein, and is one of the most important ideas he has ever given to the dental profession. He insists upon the necessity for this, and we must acknowledge the scientific accuracy of it and pay heed to it in our operative practice.

The great majority of operators, while having no fear of other forms of surgical interference of much greater significance, have a great dread of encroaching upon the apical tissues. This is something that must be overcome. If it is done with care as to asepsis, no damage is done, and our work is definite.

Methods of removing the contents of the canal. Removal of the root-canal

contents may be accomplished in several ways. The most effective method at present is by the use of alkalis or acids. I use sodium and potassium for the removal of the organic contents, and resort to acids for the removal of inorganic obstructions. However, as we approach the apical end, we should, if possible, rely entirely upon the former. As we use only microscopic amounts of sodium and potassium on our apexographer at each introduction, and as this material enters instantly into chemical combination with any organic matter it touches, the original chemical identity of each is lost, and no further destruction of tissue can occur. On this account we may safely go through the apical opening. With acids, however, we might have considerable destruction of tissue, as the acid is drawn up by capillary attraction and is not self-limiting in its action, as sodium and potassium is. The removal of all root-canal contents includes also the removal of all broken-off steel instruments, which are occasionally found left in as souvenirs of some former operation. Where it is impossible to remove such by mechanical means (which is often the case) I have found they may be dissolved out by the use of trichlorid of iodine (ICl_3). (See Figs. 1 to 5.) This is the only chemical, to my knowledge, that will attack steel rapidly and which with the proper technique may be used with safety. It forms ferrous chlorid and iodid when brought in contact with steel or iron, and both salts being soluble in water they may be washed out as formed. It is at the same time a most efficient germicide, being a combination of the two most used halogens, and I predict a wide field for its use.

V. REFILLING OF THE CLEARED CANAL.

We must replace with a filling material all tissues so removed. If these tissues are all removed, we have an empty canal or canals which will in time become infiltrated with blood serum, lymph, etc., and so will make an ideal culture tube for any pyogenic organism which

may be hemolytically deposited therein. Therefore our fifth requirement must be complied with. As we have removed the contents through to the outside extremity of the apex, we must fill to that same distance. Moreover, we have at the extremity a point where the pericementum does not cover the apex, and after pulp removal this small area must be taken care of and encapsulated by our root-filling material; or we have exposed cementum which may cause osteoclastic action, and this must be prevented as suggested.

VI. CHARACTER OF FILLING MATERIAL TO BE USED.

We must use only such materials to replace the tissues removed as are inert and insoluble in the tissue environments in which they are introduced. The only materials which I at present know to be *proved* inert and insoluble for this work are chloro-percha and gutta-percha. With these in combination, we may safely and correctly fill any canal that can be filled, with the assurance that they will work no destruction and will remain permanently.

VII. NO NOSTRUMS TO BE EMPLOYED.

We must use no nostrums for any of these purposes. The use of nostrums for any purpose in root-canal work cannot be too strongly condemned. It is not reasonable to suppose that any patent-medicine fakir would have knowledge that was not already in the possession of one or another of our related scientific professions, and if such should ever prove to be the case his product could very easily be analyzed, and its composition made known.

VIII. THE X-RAY AS AN AID IN ROOT-CANAL OPERATIONS.

We must use proper diagnostic means to determine that—

(a) *All such tissues are removed and replaced with a filling material.*

(b) *In all infected cases the surrounding tissues become and remain healthy.*

Perhaps you have noticed that my requirements are all general in character. I have endeavored to make them basic; in other words, to so state them that new methods will not affect their soundness. For instance, under our eighth division our diagnostic means are at present somewhat limited, and we may yet develop a means of fluoroscopic examination or transillumination which will supplant present methods of diagnosis, but *never* the necessity for proper diagnosis of the points mentioned.

(a) To be sure that all tissues are removed from the canal we must now depend, first, upon the tactile information we obtain during instrumentation, and second, upon a roentgenogram of the tooth obtained after inserting a sterile diagnostic wire. After removing the wire and filling the canal we then obtain another roentgenogram to see if the operation has been successful.

(b) In all infected cases we must take a subsequent picture to see if the former radiolucent area is approaching roentgenographic normality, and still later to see if it is so remaining. If in doubt after this method is used, one can always open surgically into the apical region and make a culture.

IX. SURGICAL INTERFERENCE.

We must resort to surgical interference where indicated.

(a) *Apicoectomy.* Where we have reason to believe from extensive apical necrosis that conservative treatment will not be successful, we may resort at once to apicoectomy. Or in some cases where, after careful conservative technique, the infection is not eradicated, or on account of too great a curvature of the root we could not properly fill it, we may resort to apicoectomy as a further means of eradication without loss of the root. After apicoectomy, however, we leave an area of cementum without pericemental covering, and therefore open to osteoclastic action; and as exposed cementum seems to be a special invitation to osteoclasts it would seem to be good technique to cover all this exposed cementum with

chloro-percha before closing the wound, thus absolutely preventing possibility of infection.

(b) *Exodontia*. As a final expedient we always have extraction and proper after-care of the socket to eliminate the infection.

X. SYSTEMIC CONDITIONS AND THE TEETH.

We must most carefully consider the condition of each patient, and the possible influence of our root-canal work upon the health. After all, our root-canal work is done only for the benefit of the patient, either to restore normal occlusion and masticatory ability or to remove or prevent some dental infection, and we ought to consider from beginning to end the influence of what we are doing upon the patient's health.

In cases where secondary systemic involvement is suspected or when a patient is referred for eradication of focal infection, a most complete record of the patient's general condition should be obtained before commencing operative procedure. Not only should the dentist understand the usual medical report, but if the dental profession is to accept the burden of responsibility which is being laid upon it by the medical profession, it must understand and be able to assist in the immunological reactions in diagnosis and prognosis. Dr. Rhein has already called attention to the value of the complement-fixation test. I wish at this time to call attention to other tests in which the dentist can be of great aid. The first is the anaphylatoxin test. This is an easily carried out test, and of great value in confirmation of the complement-fixation test. The dentist can obtain a culture from the infection present. This is incubated and isolated in pure culture. This antigen is then added to the patient's blood serum, incubated for one hour, and then injected into a guinea-pig. If the pig dies quickly it means that the patient's blood serum has elaborated the specific antibody which sets free the toxin of the organism in question, and the guinea-pig dies of anaphy-

laxis or protein poison. If the animal does not die it means that either the patient's blood has not elaborated the necessary specific antibodies, or infection has not become general. To determine which is the case the evidence of the other general tests must be considered.

The second test is the agglutination test. We obtain a culture direct from the dental focus. From this obtain a pure culture as before, and incubate with the patient's blood serum. If there is no agglutination obtained from this (that is, a minus report) and we have a minus complement and anaphylaxis report, this would be almost positive evidence that any infection the patient may be suffering from is not from the dental focus.

The dentist should be able to talk intelligently to the physician when consulted on such matters. He should, further, be the best able to interpret roentgenographic examinations of the oral tissues. With such a basis we shall have a better understanding of the importance of our root-canal operations and treat them with the proper regard.

In conclusion, I wish to recapitulate the ten requirements of root-canal work, so that you may have them together for consideration:

(1) We must use all possible aseptic precautions in all cases.

(2) We must use in addition antiseptic and mechanical precautions in all previously putrescent or infected root conditions.

(3) We must obtain the necessary direct access to all canals at any needed sacrifice to the crown portion of the tooth.

(4) We must remove all root-canal contents.

(5) We must replace all tissues so removed with a filling material.

(6) We must use only such materials to replace the tissues removed as are inert and insoluble in the tissue environments in which they are introduced.

(7) We must use no nostrums for any of these purposes.

(8) We must use proper diagnostic means to determine that—(a) all such tissues are removed and again replaced;

FIG. 1.

FIG. 2.

FIG. 3.

FIG. 4.

FIG. 5.

FIG. 6.

(b) in all infected cases the surrounding tissues become and remain healthy.

(9) We must resort to surgical interference where indicated: (a) Apicoectomy. (b) Exodontia.

(10) We must most carefully consider the condition of each patient, and the possible influence upon their health of our root-work.

I now show a few lantern slides demonstrating these principles as applied to the actual root-work in my everyday practice. We often hear the criticism that only single-rooted teeth are shown. I here show only cases of multi-rooted teeth, or in which more than one single-rooted tooth has been so filled in the same film, to prove that these cases are not selected ones showing only hap-hazard success, and further, that the same results are consistently obtained in the posterior teeth. I show in Fig 15 no

less than eight root-apices properly filled, all in the one film.

The Practice of Dentistry in the Army and in Civil Life: A Comparison.

By Lieut. K. F. SMITH, D.R.C., Camp Grant, Ill.

(Read before the Camp Grant Dental Society. February 15, 1918.)

I REGRET that this subject, so fraught with possibilities, has not been placed in more capable hands than my own. I am sure that my association with army dentistry is of too recent origin to enable me to make a very comprehensive comparison, and if, perchance, I wander somewhat from my subject, I ask your indulgence.

It is my belief that in choosing us from among the many dentists of this country who have volunteered their services our country has paid us the highest compliment possible for a dentist to receive. The dentist in army service, or, if I may use the term, the "army dentist," must be conscientious to the highest degree. His patients have no choice; they must accept his services, be it to their liking or otherwise. This factor does not hold true in civil practice, where the dentist who errs seriously in judgment, or is rough and unnecessarily cruel, quickly loses his practice, and finds he must take up some other field of endeavor.

As army practice in cantonments, the only type of which I am qualified to speak, brings us into contact only with the male sex—usually men of a very hardy type—and much authority has been placed in our hands in our relations with these men. I feel that it behooves us to watch ourselves closely that we do not abuse this privilege, and bring discredit to ourselves and to dentistry in general.

We have been selected and placed in our present positions, gentlemen, with a definite object in view—to place the

mouths of the men in our respective commands in the best possible shape, with as great celerity as possible. Here again we find a line of demarcation. The best possible condition, in the army parlance, differs materially from that in civil practice. Estheticism must be almost entirely subordinated to the more important phases, masticatory ability and absence of all focal infection. You will notice, gentlemen, that I qualify my statement by the word "almost." I feel that no amount of time or sacrifice is too great to make in saving these infected teeth where the disfigurement would be marked, and our means of restoration unlimited, providing, of course, that the infection is ultimately curable. In all probability, in civil life, the mere mention of removing such a tooth would cause your patient to look elsewhere for dental treatment.

The assertion that in the army we are trying to tear down our practice and in civil life to build it up might easily be misunderstood. In the army, it is true, we are trying to tear down our practice by the rapid elimination of dental diseases in our commands. This principle also holds true in civil practice. It is the successful elimination of dental diseases from our patients that enables us to increase our practice.

One marked difference that I have noted is the coolness and courage with which these men of the army face dental operations; the same class of men six months ago, in my practice, did not show the same stoicism. I attribute it to their soldier's sense of pride, their good health, and disciplinary training.

Our Government has given us a very complete and efficient equipment to perform the work it wishes us to do, and there is no excuse for any but the highest class of dental treatment.

The situation often confronts us of badly broken-down bicuspid or molar teeth which in civil practice could be very nicely restored with a gold crown, or possibly an inlay. These teeth should not be lost; anchorage of some kind must be secured and the restoration made in some manner. Let us avoid, if possible, gentlemen, the accusation in future years, "If you had a toothache in the army, they pulled the tooth out."

I do not feel that there should be any

marked difference between dentistry as practiced in the army and that of civil life, save in the limitation of our restorational material.

Good dentistry is good dentistry everywhere; the same careful consideration, tact, kindness, and human interest, so essential to success in civil life, will win success for dentistry in the army. For, after all, the final verdict upon the success or failure of dentistry in the army is going to be read in the future years, not only in the archives at Washington, but also in the hearts and minds of some two million or more free American citizens who at present constitute, or will shortly constitute, the American army.

A Preliminary Report upon the Temporo-mandibular Articulation in the Human Type.

By H. J. PRENTISS, M.D., Iowa City, Iowa,

ANATOMICAL LABORATORY, UNIVERSITY OF IOWA.

THE bony structures entering into the temporo-mandibular articulation are the glenoid fossa and the eminentia articularis of the squamous portion of the temporal bone above and the condyle of the mandible below. Between the temporal surface and the condyle is interposed a fibro-cartilage called the meniscus. Such a fibro-cartilage is present wherever is found one bone moving over a considerable surface of another—otherwise there would be a rattling around in the joint. Besides the mandibular articulation we may instance the sterno-clavicular and femoro-tibial or knee joint. In the latter case we observe the tibia moving around the condyle of the femur as the leg is flexed or extended. This articulation has two purposes, one to carry the weight of the body as we stand erect; the other, flexion of the leg upon the thigh in walking—a very different function indeed.

The inferior surfaces of the condyles of the femur are arcs of large circles, so large that they present almost a flat surface for carrying the weight of the body in the erect position (Fig. 3). The posterior surfaces of the condyles rapidly diminish, developing the arcs of circles of small radii (Fig. 4). This is to facilitate rapid flexion of the tibia upon the femur, as no weight is carried in this position. The tibial articular surfaces do not vary, so that the same tibial surfaces are in apposition to the arcs of the small circles as well as the arcs of the large circles. This would naturally result in great irregularity in the movements of this joint if nature did not provide some means to adjust the condition, which she has accomplished by developing the meniscus. If we study the early embryonic lower extremity, we observe that the mesenchyme at the site of the future knee joint differentiates into the

anlage of the fibro-cartilage, with two spaces separating it from the anlage of the femur and tibia (Fig. 1). This beginning fibro-cartilage becomes a true

muscle pull, as of course no weight has been brought to bear on these surfaces. In the adult this meniscus has become a ring of fibro-cartilage, with a large

FIG. 1.

meniscus separating the femur from the tibia.

At birth (Fig. 2), we observe that centrally the cartilage has disappeared, leaving

Adult knee joint. Leg flexed, to show migration of semilunar cartilage, thus keeping opposed surfaces in apposition.

ing a circular opening; this is relatively a small opening as compared with the condition in the adult joint. Undoubtedly this early atrophy is due to powerful

central opening. This ring of cartilage is called the semilunar cartilage (Figs. 3 and 4). I think we can interpret this as due to the great pressure brought to bear in assuming the erect position; for, as we know, fibro-cartilage or any adult cartilage is non-vascular, and will therefore easily retrograde if undue pressure be brought to bear. This retrograde process in the knee joint is normal.

It may be of interest to note the significance of this condition in this joint. With the tibia extended on the femur as in the upright position, the semilunar cartilages are pressed to the extreme periphery of the articular surface, and the large arc of the circle on the femur is in continuous apposition with the tibia plus this cartilage, which in a sense acts as a stuffing to keep everything snug. With the tibia flexed (Fig. 4) the small arc of the circle on the femur is applied to the same large surface of the tibia. Here again the analogy of the stuffing applies, for air-pressure forces the semilunar cartilages inward as the lesser sur-

faces recede from the greater, so that again continuous apposition is accomplished. We see therefore in the knee joint a retrograde absorption of the

and the condition of the semilunar cartilages is simulated. However, the fibro-cartilage of this mandibular joint does not show the marked thickening and

meniscus which is necessary to the normal function of this joint.

The sequence of events just followed in this joint may be traced in the mandibular joint, only here it becomes pathological with the loss of teeth. This joint differs from the knee joint in the fact that by the eruption of the teeth the surfaces are kept apart, and with their loss the muscle pull approximates these surfaces with atrophy of the meniscus. The condyle of the mandible glides over the eminentia articularis from its resting position in the glenoid fossa (Figs. 5 and 6). Therefore a meniscus develops.

Fig. 7 is a section of a fetus about five months old. Note the meniscus, and how well the musculature is developed. At birth, though the teeth have not erupted through the buccal epithelium, yet they are present, and the alveolar processes of the maxilla and mandible are large, so that the condyles are prevented from pressing against the temporal articular surfaces. Therefore the meniscus is not obliterated, but persists as a continuous fibro-cartilage. With the loss of teeth the alveolar process resorbs,

thinning which we find in the adult (Fig. 8).

In the adult the molding of the meniscus is very pronounced (Fig. 9).

FIG. 7.

Coronal section of a five-month fetus, showing the mandibular articulation with the meniscus well formed. External pterygoid attached to this joint. Soft palate separating nasal pharynx from buccal cavity.

In the glenoid fossa the meniscus is thick, thinning out on the dorsal surface of the eminentia, but becoming thicker in front of the thrust of the condyle

(Fig. 9). This condition is due to the eruption of the teeth withdrawing the

plasia due to the erupting teeth relieving the meniscus from pressure.

FIG. 8.

FIG. 9.

FIG. 8: Histological section of mandibular joint at term. The condyle is almost globular. The eminentia articularis is but a ridge. The meniscus shows little molding. Drawn to twice the normal.

FIG. 9: Histological section of adult mandibular joint. Meniscus well over the eminentia articularis. Marked molding on under surface. Upper head of external pterygoid attached to meniscus; lower head attached to neck of condyle. (Compare with photomicrograph, Fig. 18.)

FIG. 10.

mandible from the maxilla, and therefore the condyle from the temporal surface. As early cartilage is relatively vascular, we may conclude that there is a hyper-

In a dry skull with perfect teeth (Fig. 10) the condyles are separated from the temporal surfaces when the teeth are in occlusion. A wax mold may be made

which is a perfect model of the fibro-cartilage, with the thick portion in the glenoid fossa and the thin portion over the eminentia. This beautifully illustrates how the teeth relieve the meniscus from pressure and consequently from atrophy.

EFFECT OF LOSS OF TEETH UPON THE MENISCUS.

If, however, the teeth are removed, the condyle is pulled upward by the powerful musculature, and pressure is brought to bear upon the meniscus with a resulting atrophy varying from a small opening to a ring of cartilage in many ways resembling the semilunar cartilages of the knee. This pressure in old cases is carried to such a degree that not only is the hyaline articular cartilage covering the condyle and the temporal surfaces destroyed, but also the bones themselves show marked pressure atrophy (Fig. 11). Here the glenoid cavity is so excavated that the plate of bone between the condyles and the brain cavity is practically *nil*. (Note how the neck of the condyle has been excavated by pressure on the eminentia, indicating that there has been a loss of any gliding motion, and that the condyle only rocks in the glenoid fossa.)

This department has observed this condition of varying atrophy for some time, and this spring Dr. Richard Summa, professor of prosthetic dentistry and orthodontia in the dental college of the University of Iowa, visited the anatomical laboratory to carry farther our observations. He observed the condition of the teeth in the various cadavers, made an estimate of the pressure on the meniscus, and then we dissected the joint. In every case we found pressure atrophy where it was expected. Again, when loss of teeth was unequal on the two sides we found unequal atrophy of the two fibro-cartilages. Fig 12 shows sketches of a number of these cases.

ANATOMY OF THE TEMPORO-MANDIBULAR ARTICULATION.

As to the anatomy of the joint, with emphasis upon the meniscus, the menis-

cus extends from the anterior limits of the eminentia articularis backward to the Glaserian fissure, to which it is loosely attached by the capsule (Fig. 9). On its upper or temporal surface this meniscus

FIG. 12.

presents a continuous smooth surface, permitting it to glide freely forward. At its limits it is attached to the temporal bone by a loose capsule. Its under surface presents a very different picture; it is divided into two portions, an anterior

part into which is inserted by strong fibrous fasciculi the external pterygoid, condyle of the mandible (Figs. 9 and 13).

FIG. 13.

FIG. 14.

FIG. 13: Viewing meniscus and capsule from beneath. The condyle on right has been removed. (Normal.)

FIG. 14: View similar to FIG. 13. Here the meniscus in the glenoid fossa has absorbed away, leaving the capsule and pterygoid muscle attachment. To left shows the ring of the meniscus with much-eroded bone of condyle.

FIG. 15.

FIG. 16.

FIG. 15: View from below of glenoid fossa, eminentia, etc., with only the condyles fitting in snugly against the eminentia, but allowing free play laterally, backward. The apex of the triangle is at the symphysis mentis.

FIG. 16: Same view, but with condyle on the left moved on the eminentia but the lateral aspect of the condyle on the right rotated backward.

and a posterior, rather shallow smooth concave surface for lodgment of the

Note in front of the concave surface a thick portion of the meniscus preventing

forward displacement of the condyle on the meniscus. The capsule at the neck of the condyle is attached to the periphery of this posterior smooth surface, thus confining the condyle to this portion of the meniscus, and this portion only (Figs. 9 and 13). The articulation between the condyle and the meniscus is therefore a condyloid joint. At the same time the meniscus glides forward, due to the direct pull of the external pterygoid. We can say, therefore, that the mandibular articulation is a gliding condyloid joint (Figs. 5 and 6).

In the specimens sketched (Fig. 12) some show a complete atrophy, excepting anteriorly, where the pterygoid is attached; others show a ring of cartilage persisting, of various degrees of thickness; from these they show changes down to a small opening. These cases of lesser atrophy, as Dr. Summa pointed out, begin at the lateral limit of the meniscus, and then they pass inward to involve the entire meniscus.

If we examine the condyle we note that the articular surface abruptly turns downward at the lateral aspect or where the condyle is broadest (Figs. 15 and 17). This is probably due to the tilting of the jaw during lateral motion, as the condyle of one side is depressed when passing over the eminentia (Fig. 17). Again, though the glenoid fossa is wedge-shaped, being narrow medially and broad laterally, and the condyle is also narrow medially and broad laterally, we note that there is considerable play posteriorly at the lateral limit (Fig. 15). That is, though the inner aspect of the fossa and condyle are closely approximated, the lateral aspects are not, the posterior surface of the condyle in this lateral region not being in apposition to the glenoid fossa in the region of the post-glenoid ridge (Fig. 15). This probably permits posterior displacement of the lateral portion of this condyle as the opposite condyle moves forward and inward over its eminentia articularis. In other words, the center of rotation is not at the extreme lateral limit of the condyle, but approximates the place where the neck of the ramus joins the condyle.

We therefore have a lateral short arm

passing backward as the medial long arm passes forward (Fig. 16). The result is that a twisting movement is ap-

FIG. 17.

Schema. On the left, condyle depressed by eminentia articularis; on the right it is still in glenoid fossa. To show molding of the meniscus on the right and rotation of condyle due to tilt of the jaw.

plied to this lateral portion of the meniscus, so that marked pressure is applied to this point with loss of teeth. This may account for pressure atrophy beginning at this lateral point.

This department is experimenting with dogs in an effort to determine the ra-

FIG. 18.

Photomicrograph of section of adult mandibular articulation. (Compare with pen-and-ink sketch, Fig. 9.)

pidity with which fibro-cartilage will atrophy under pressure. I hope to make a final report on this matter. As far as I can judge, these observations point out to the dentist that the moment pressure

is brought to bear on the mandibular articulation by loss of certain teeth, immediate steps should be taken to prevent retrograde changes in the joint. If our experiments on the dog are successful, it will give the dental technician some knowledge as to the leeway given him in preventing loss of tissue.

As to the mechanism of the mandibular movements, I would refer you to an article by Dr. Frederic Lord, professor of anatomy at Dartmouth College, in 1913, who visualized them in the laboratories of the State University of Iowa. Under the present procedure, as I understand it, the dentist prepares his artificial

dentures when there is a partial or a complete loss of the meniscus; the result is, that instead of the condyle being in apposition with a smooth gliding meniscus it projects into a cavity. The first condition may be likened to a man being drawn forward while sitting in a smoothly running buggy; the second condition may be likened to the result of a runaway, when the buggy is destroyed and the individual, entangled in the lines, is bumped over the ground. Lastly, and with hesitancy, I might say the dentist in making his plates seems to me like a mechanic who adjusts the lock of a door when the hinges are off.

The Importance of the Inter-articular Fibro-cartilage of the Temporo-mandibular Articulation.

By **RICHARD SUMMA, D.D.S., Iowa City, Iowa,**

PROFESSOR OF PROSTHETIC DENTISTRY AND ORTHODONTIA, COLLEGE OF DENTISTRY,
STATE UNIVERSITY OF IOWA.

EVERY text-book on dental prosthetics devotes a chapter to the anatomy of the temporo-mandibular articulation, and many laudable efforts to devise a method of reproducing the condyle path upon dental articulators are recorded. Only the osseous structures of this articulation, however, have been given any practical consideration in the attempts to construct a mechanical apparatus which would imitate the complex mandibular movements. The soft tissues, of which the inter-articular fibro-cartilage is the most important, have been almost entirely disregarded. It is true that all textbooks mention and vaguely describe this meniscus, nevertheless one is reminded of the mention which occlusion of the teeth was given in treatises on orthodontia prior to the days of Dr. E. H. Angle's recognition and ap-

plication of this anatomical factor as the basis of all orthodontic procedures.

Unfortunately, like other parts of the human anatomy which are of primary and almost exclusive interest to the dentist, the meniscus has been given honorable mention by anatomists in the description of the temporo-mandibular articulation, and there the matter rested. It is quite in keeping with the natural order of things that each specialty should seek and develop the knowledge pertinent to its own progress, and thereby strengthen itself. It is needless to state that the prosthetist's and the orthodontist's chances for studying this articular fibro-cartilage *in situ* are few and far between. It becomes necessary not only to obtain access to an anatomical laboratory, but also to elicit the assistance of an anatomist, and hence I believe the ef-

forts of Dr. Henry J. Prentiss, professor of anatomy at the State University of Iowa, will readily meet the appreciation of the dental profession.*

In a recent discussion relative to mandibular movements the disputants agreed that the temporo-mandibular articulation (and this must include all the structures concerned in this articulation) is originally shaped in response to the occlusion of the teeth. It was likewise agreed that malocclusion and loss of teeth produce corresponding changes in the temporo-mandibular articulation.

The investigation of Dr. H. J. Prentiss confirms these assumptions; furthermore, it calls attention to the fact that the meniscus is not the least important component of the temporo-mandibular articulation. The meniscus is that component part of this articulation which first receives the stimulus and also sustains the first impact to this joint resulting from the function of mastication.

Dissections of this joint clearly reveal the fact that following the loss of a few teeth the meniscus becomes thinned; following the loss of a larger number of teeth the meniscus is perforated, while following the loss of all teeth the entire upper surface of the condyle becomes denuded of inter-articular fibro-cartilage. Immediately following the perforation of the meniscus, absorption of the correspondingly exposed surfaces of the condyle and the glenoid fossa begins, and thus the change and reshaping of the temporo-mandibular articulation take place. It may not be amiss in passing to reiterate and emphasize the observation in the material thus far examined that the perforation of the meniscus always begins in the same location, namely, the external lateral angle.

From all that can be gleaned from the writings and discussions of the subject, the prosthetist and the orthodontist happily assume that this joint will readapt

itself to the occlusion which their handicraft sees fit to establish—the one with artificial dentures and bridge work, the other with a corrected or improved occlusion of the natural teeth. However, practitioners of these branches of dentistry have frequently had occasion to wonder why such blissful dreams rarely come true. After enjoying the privilege of studying the anatomical material from which Dr. Prentiss derived his conclusions, one should be pardoned for wondering why the prosthetist's devices ever give reasonable satisfaction in any instance. At the same time one cannot help but give renewed expression of thankfulness to tolerant mother Nature for granting as many reasonably good results to orthodontic operations which involve a change in the temporo-mandibular articulation.

The prosthetist's efforts are expended on individuals of mature years when destructive processes of osseous structures are more the order of the day than constructive growth. If cognizance is also given to the fact that a non-vascular organ, such as this inter-articular fibro-cartilage, has no recuperative or reconstructive power, then we can be little short of amazed by the assertion that it is the prosthetist's privilege and duty to establish an articulation of artificial dentures irrespective of the temporo-mandibular articulation of any given case, because the occlusion of the teeth of artificial dentures decreed by the prosthetist will induce the matured structures of the temporo-mandibular articulation to grow as he wishes them to grow. The difficulty with this class of prosthetists has been that they based their arguments upon what they could do, because that is plainly visible, giving no thought to conditions encountered in the living subject which are not necessarily amenable to their mechanical efforts.

The prosthetist is at a disadvantage because his restorations must be adapted to abnormal condyle paths of infinite variations. In the largest proportion of cases of artificial dentures and bridges we must expect to deal with thinned or perforated menisci. It is a universal ex-

* [See paper by Dr. Prentiss entitled "A Preliminary Report upon the Temporo-mandibular Articulation in the Human Type," at page 505 of the present issue of the DENTAL COSMOS.—ED.]

perience that artificial dentures will permit of exerting only a small fraction of the force capable of being exerted by natural teeth. This has been attributed solely to the mobility of the bases upon which artificial dentures must necessarily be constructed. While this is unquestionably an important factor, may we not assume that the loss of power and masticating efficiency is also in part due to an instinctive hesitation on the part of the patient to exert more force, to avoid at least a feeling of discomfort, not to say pain? Occasionally, patients for whom apparently well-occluding bridges have been made will complain of a loss of masticating power or of an interference with the freedom of mandibular movements, or according to a recently published article, that the bridges "feel like stone walls." These complaints have been ascribed to a neurotic tendency in the patient, or to excessive peevishness, etc. However, such conditions are more correctly explained by the knowledge that in such cases the normally intervening fibro-cartilage has been irreparably destroyed, and as a result the denuded bone surfaces of this articulation have been forced into frictional contact by this so-called improved occlusion.

There are types of malocclusion which present a short horizontal ramus or body of the mandible, usually characterized by a receding chin. These cases suggest the necessity of carrying the mandible forward by means of intermaxillary force or by means of a bite plane, and the

operator has proceeded to "jump the bite" in the endeavor to produce a change in the temporo-mandibular articulation which would permanently compensate for the shortness of the horizontal ramus.

Practical experience in such cases proves the impossibility of achieving the desired result, and a study of the anatomy of the articulation stamps such an orthodontic operation as questionable. Whatever improvement is possible in these cases is due to a correction of the occlusion of the teeth and the consequent molding of the body of the bone.

It is immaterial whether or not, at this time, the difficult task of constructing a device upon which the mandibular movements can be imitated has been accomplished. Nevertheless, a sincere appreciation is due the men who have intuitively or otherwise recognized the futility of placing the cart before the horse. Most deserving of mention in this connection is the work of Dr. Gysi.

The argument that some of the dentures constructed according to any of the methods which ignore existing natural conditions are successfully worn, or that fixed bridge work which has violated the important demand for mobility of the teeth has been paid for and worn by that same patient individual, reminds one of the argument that individuals whose wounds have been treated by applications of cowdung have survived in the struggle for existence. If scientific men were content to depend upon such reasoning it would indeed be deplorable

Collapse under Anesthesia due to an Enlarged Thymus Gland.

By ISADOR H. CORIAT, M.D., Boston, Mass.

From the Surgical Department of the Forsyth Dental Infirmary for Children.

IT has long been known that certain individuals, particularly children, with enlarged thymus glands react badly to anesthetics, infectious diseases, mechanical shocks, and to the injections of sera (antitoxin). Extirpation of the thymus gland in dogs may lead to a retarded growth of the bones, enlargement of the epiphyses, and a tendency of the bones to bend, in fact a condition which strongly resembles the osseous changes in rhachitis. The relation of the thymus gland to bony changes in children and the reaction of such individuals to narcosis is less well known. Intimately associated, also, with the occurrence of an enlarged thymus gland is the enlargement of lymphatic tissues elsewhere in the body. Cases of this type may show collapse or sudden death under anesthesia, even when no mechanical pressure by the enlarged thymus gland seems probable. These cases of *mors thymica* in children have been variously explained as being due to mechanical pressure, compression of the trachea, disturbances of the sympathetic nervous system, aplasia of the cardio-vascular system, etc., but none of these explanations have cleared up all the facts in the condition.

The following case is reported as indicating in an admirable manner the relationship of an enlarged thymus gland to rhachitic changes in the bones, to attacks of what may be termed thymic asthma, and finally to thymic collapse under light anesthesia.

L., a colored boy four years of age, was brought to the Forsyth Dental Infirmary

to be operated on for adenoids and tonsils. The clinical record for anesthesia showed the following: Weight 34 lb.; height 3 feet; temp. 98.6°F.; pulse 100; respiration 24; hemoglobin 80 per cent.; blood pressure 96-44. The heart, lungs, and urine were negative. Some post-cervical glands were present. During the preparations for anesthesia the head of the child was not hyperextended, so that the collapse which followed could not have been due to a mechanical obstruction from an enlarged thymus.

After three inhalations of nitrous oxid-ether mixture, the patient suddenly ceased breathing; there was a sudden collapse, and breathing was resumed only after several minutes of artificial respiration. The operation was postponed, since a status thymo-lymphaticus was suspected, and to this end the patient was submitted to further study.

According to the history, the child had bronchitis when one year of age, and at this time he had three convulsions in one day. None have occurred since. Since then he has had several attacks of difficulty in breathing, with hoarseness (probably thymic asthma). Walking has been delayed on account of rhachitis.

Physical examination. A rather underdeveloped but fairly well-nourished negro boy, who was markedly rhachitic. The head was square, the epiphyses enlarged, and a rhachitic rosary could be felt on the ribs. Circumference of head 52 cm., biparietal diameter 15 cm., antero-posterior diameter 17 cm.: cephalic index 88.8 per cent. The palate was

normal, the teeth were typical for the age of four, and showed no defect of calcium metabolism such as might be expected in a rhachitic child or in thyroid or parathyroid deficiency. An umbilical hernia was present. The pupils and knee jerks were normal. There was no increase of subcutaneous fat.

Percussion over the chest in the region of the second and third interspace showed increased dulness, particularly to the right, where the dulness was about a finger's breadth in width. A radiograph of the chest disclosed a shadow on both sides of the upper portion of the sternum.

Both the percussion signs and the radiograph were extremely suggestive of an enlarged thymus gland, and this was further emphasized by the history of the asthmatic attacks, the rhachitic development, and the sudden collapse under light anesthesia. Since the opening of the Forsyth Dental Infirmary there have been a total of 2140 operations under complete anesthesia, and the above case was the only instance of collapse, thus demonstrating that, in our material at least, an enlarged thymus gland with the typical clinical symptoms is extremely rare.

416 MARLBOROUGH ST.

A Type of Denture for Army Use.

By Lieut. E. H. RAYMOND, M.C., U.S.R.,

NO. — (PRESBYTERIAN U. S. A.) GENERAL HOSPITAL, BRIT. EXP. FORCE, FRANCE.

IN the early spring of 1917, in connection with work being done for recruits by the Preparedness League of American Dentists, the attention of the writer was drawn to the desirability of modifying the type of denture used in civil life to suit army conditions. At that time removable dentures were a bar to the admission of candidates for voluntary enlistment in the army, on the ground of the liability of such dentures to breakage, and with a view of obviating this objection the form of appliance about to be described was constructed. Since the arrival of the Presbyterian Base Hospital Unit in France, in June 1917, this appliance has been extensively used in the dental service of that organization. Dentures so made have proved to be practically unbreakable, accurate in adaptation, simple to construct, and their cost to be but a small fraction of that of the vulcanite and porcelain type.

The percentage of breakages of den-

tures under the conditions of trench life is high. The time necessary for the collection of extensive statistics has not been available, but the writer has been informed by officers of the British dental stations where denture work is done that repairs are a very important item, and even in this hospital, where such work is merely incidental, the number of broken plates brought in for repair has been notable. A recent census of 127 patients, taken at random in the wards, showed that 23 had vulcanite dentures, and of these 23 all but 7 were broken, 38 porcelain teeth having been lost, and in 3 the vulcanite base itself had been split. In several of the cases abrasions of the mucous membrane were present from the rough edges, and in one a well-marked case of Vincent's angina of the lip was found at the site of irritation from the broken plate.

The fracturing of porcelain is often due to the hard biscuits served in lieu

of bread in the army ration. Many plates are also broken which have been removed from the mouth at night, the cramped space and the poor lighting of

FIG. 1.

tents and huts making such mishaps far more common than in civil life. The intentional breaking of dentures, with the hope of getting out of the line, like the self-inflicted wound, is probably a rare

FIG. 2.

occurrence. With the form of plate described it would be still rarer.

The denture in use in this hospital is made entirely of metal, by the casting process. Commercial aluminum has been found the most suitable material. It

makes a sharp casting, has good edge strength for cusps of teeth, great tensile strength, withstands the secretions of the mouth, and is cheap, the present price in France being 8 fr. per kilo (about 75 cents per pound). An average all-metal denture weighs some 22 gm., making the cost of the metal some six or seven cents.

TECHNIQUE.

Clasps, where necessary, are soldered to tags in the same manner as for vulcanite work. From motives of economy nickel silver, heavy plate or half-round wire, is used for clasps, except in cases where considerable spring is required; in such cases clasp gold is used. An efficient substitute for clasp gold, at a low price, is a desideratum for army work.

Fig. 1 shows a very common case. The wax base-plate, made from pink paraffin wax, is molded to fit the model, the clasps are fastened to the base-plate with hard wax, and wax teeth, made as described below, are mounted in proper

FIG. 3.

articulation. With a suitable selection of wax teeth at hand this is a simple matter, the occlusal surface and base of the wax tooth being easily carved to form. At this stage the pattern is tried in the mouth, and any necessary change made in the articulation. Sprues made from one-fourth-inch strips of base-plate wax rolled into cylinders are then attached as in Fig. 2, and the piece invested and cast. (See Fig. 3.) Various casting devices have been tried, but for work of this kind the elaborate suction or com-

pression machines have been found quite superfluous. The apparatus at present in use consists of a piece of brass tubing, 5×5 in., in which the pattern is invested, and an enameled soapdish, which fits the tube loosely like a tin box lid and which is half filled with wet asbestos. The metal is melted with a coarse brush flame, and forced into the mold by hand pressure with the "lid." A similar device

FIG. 4.

FIG. 5.

FIG. 6.

made from sections of brass shell cases has been described in the February issue of the *British Dental Journal*, and would doubtless prove satisfactory.

For the forming of the wax teeth, extracted teeth of suitable shapes are selected, and modeling composition molded to the roots, as in Fig. 4, in the shape of a truncated cone. From this a hollow mold is obtained in fusible metal, or still better, in Weinstein's artificial stone. Porcelain teeth, or the rubber teeth of the Sharpe seamless crown system, can be used as patterns; the molding flask

in the latter outfit makes an excellent implement for forming the hollow mold.

FIG. 7.

Wax replicas of suitable natural teeth are preferable, as the cusping is sharper. The wax teeth (Fig. 6) are best made in

FIG. 8.

inlay casting wax, but ordinary base-plate wax can be used with good results. The base-plate wax drags more in carv-

FIG. 9.

ing, however, and is less satisfactory for the final articulation of the pattern in the mouth. When the molds have been

made, a stock of wax teeth can be poured in a short time, and the work can be done by untrained assistants. If artificial stone molds are used, care should be taken that they be soaked in water before pouring in the wax.

In attaching the wax sprues it is necessary that the side branches meet the main sprue at an angle, in order that gravity may assist in the flow of the molten metal. Full upper plates may be cast of the thickness of a single sheet of base-plate wax by running two, or for a large plate, four, branch sprues from the main stem to the heel of the plate.

After casting, the sprues are best removed with a mechanical saw, vulcanite files and engine stones being used for finishing. Carborundum powder on felt

wheels is excellent for surfacing, and the metal takes a high polish with rouge.

All types of restoration have been made, including full upper dentures with all-metal teeth. The appearance of these dentures is an objection, although for war service that consideration should not be allowed to outweigh efficiency. A combination of six porcelain anterior teeth with cast-metal bicuspid and molars makes an excellent denture, where the time for vulcanizing can be spared. (See Fig. 7.)

In partial lowers, such as the case shown in Fig. 8, which would be a very fragile plate in vulcanite, and particularly for close-bite cases, such as Fig. 9, this type of denture is especially well adapted.

CORRESPONDENCE

More Anent Standardization.

TO THE EDITOR OF THE DENTAL COSMOS:

Sir,—Your editorial in the December issue of the DENTAL COSMOS regarding "Standardization" is much to the point, and I am in full agreement with it. I have often wondered why so much time, labor, and material was put into various instruments of all kinds of patterns which may have no sale, or even prove a loss. The nearer the dental profession approaches a standardized method of practice, the closer will it come to perfection.

I should also like to ask why the various methods of teaching in the dental colleges have not been brought nearer to a standard? A graduate who has his diploma and has passed a state board of examiners should be able to practice in any state without further examination.

Either a state certificate should be recognized in all the states, or there should be one board whose certificate is recognized in every state. This is undoubtedly a question for the National Association of Dental Faculties, and I should very much like to see the present conditions altered.

To a foreigner the conditions referred to are most confusing, and give him the impression that there must be a varied lot of good, bad, or indifferent education in the United States—and such a question should not be raised. The English L.D.S. is recognized anywhere in the British Empire, and so it should be with the D.D.S. in the U. S. A.

Yours truly,

L. N. SEYMOUR, D.D.S., L.D.S.

I SHARIA EL KADI EL FADEL,
CAIRO, February 15, 1918.

"Technique of Root Amputation."

TO THE EDITOR OF THE DENTAL COSMOS:

Sir,—The article by Dr. Prinz in the May issue of the DENTAL COSMOS is presented in his usual masterly style and has undoubtedly been read by hundreds of your readers with the greatest interest. There are a few points, however, in the paper that are not perfectly clear to the writer, and believing that scores of others must also be in the haze, this letter is written in the hope that Dr. Prinz will make them clear.

(1) After the cavity is sponged and appears "as clean as a billiard ball," why should its surface be painted with iodine? What does the iodine do to this perfectly clean and sterile surface?

(2) What action upon this iodized clean and sterile surface has the surgical powder?

(3) The writer says that when a broken instrument is in the canal, it is sometimes necessary to "push the obstructing agent back into the canal."

Let us now analyze the conditions obtaining. The root-canal and zone surrounding the root-end are filled with organisms, etc. The end of the root is cut off, "the obstruction pushed back into the canal," the necessary curetting is thoroughly done, and the wound is practically closed. The bony sac containing the granuloma has been rendered practically free from infection, but what of the infected canal opening into this sterile cavity? Why does not the cavity become reinfected at once from the infected canal? And suppose, later on, in attempting to extricate the broken instrument—which is always more or less difficult—it should be pushed out of the canal, and, infected as it is, lodge in the

area beyond the root-end? As a matter of fact, if the instrument could be removed through the pulp cavity after the amputation of the root-end, why was it not done in this manner before the amputation?

This whole procedure appears so inexplicable that I am sure many of your readers will be glad of an explanation.

"Success" is merely a relative term, as is well known. Many a surgeon has been discussing the details of a successful operation while the friends of the subject were putting flowers on the grave. When, therefore, Dr. Prinz reports two hundred cases without a *single failure*, it surely is in perfect order and without the slightest disrespect to the writer that we ask, What constitutes success and what constitutes failure in this operation?

For thirty years the writer has been advocating the use of oxychlorid for the filling of root-canals, and so few appear to appreciate its advantages that it certainly is reassuring to have a man of Dr. Prinz' known ability indorse its use.

Apicoectomy, as it is most commonly called, appears to be of so very much interest to the entire profession today that it is hoped this discussion of Dr. Prinz' paper will be accepted in the spirit in which it is offered. With many men it appears to be a commonplace operation; many others are contemplating taking it up. Dr. Prinz' paper must appeal to the latter class, and with these doubtful points more fully explained by him, it should furnish all novices with all the instruction they desire.

Respectfully,

C. EDMUND KELLS, D.D.S.

NEW ORLEANS, May 3, 1918.

PHILADELPHIA, JUNE 1918.

EDITORIAL DEPARTMENT

Industrial Dental Service.

THE conspicuous progress which has characterized dental activity since our country entered the world struggle in the cause of democracy is without parallel. To provide for our military forces the benefits of dental and oral surgical service has not only taxed dental resources to the limit for the time being, but the demand, implying as it does practical recognition by our governmental administration of the indispensable character of dental service in the efficient conduct of the war, has stimulated wide interest in the larger problems of dental service and the importance of dental and oral conditions as related to the general health.

As a direct consequence of the growing interest in dentistry as a health factor and the direct bearing of mouth hygiene upon human efficiency, the question of the economic relations of dental

welfare service in the productive industries is a problem which is more and more engaging the attention of industrial interests. From philanthropic motives much has been done toward bringing dental service, especially in the larger centers, within reach of that large portion of our population that is financially unable to pay for dental service. Municipal clinics, public school and dental college clinics do much in taking care of the dental ills of those unable to pay a normal fee for dental care. The active propaganda which has resulted in the wide dissemination of knowledge of the importance of oral hygiene has produced results which cannot fail to accomplish much in improving the general health standard of our population.

It is to be noted, however, that the animating motive of the general oral hygiene propaganda was, in its initial stages at least, largely humanitarian and philanthropic. As experience began to bear fruit it soon became evident that reasons other than prevention and relief of suffering justified the claims of dental service for consideration as a public welfare measure. The relief of dental disorders was quickly seen to have eliminated a factor of physical disability which, particularly in the case of the unhygienic mouth, constituted a positive interference with physical and mental efficiency. Dental and oral hygiene work in public schools demonstrated the improvement which practical oral hygiene produced in the mental and physical efficiency of the pupils, and the relief of many cases of actual retardation due to dental defects among school children furnished conclusive evidence of the dental origin of their retardation. It is today well recognized that humanitarian considerations alone amply justify the encouragement if not the practical enforcement of oral hygienic measures among children of school age, but in consideration of the fact that by far the greater number of them are educated at the expense of the taxpayer, and that retardation by reason of physical or mental disability entails an augmented tax for educational purposes, the economic factor becomes an added and cogent reason for effective oral hygiene work among public school children.

It is this economic element that is stimulating an active interest in the industrial phase of oral hygiene work. The managers of business enterprises are sensitively sympathetic toward any and all plans and activities that give fair promise of reducing costs

and increasing efficiency. The conviction is growing that the working capacity of a body of employees as to both kind and amount of output is directly related to their physical and mental health standards. Hence the rapid growth of various phases of welfare service in connection with large business establishments. Among these, dental service is taking its proper place.

At the Congress of the National Safety Council held in Detroit in October 1916, Dr. Lee K. Frankel of the Metropolitan Life Insurance Co. of New York presented a report on "Dental Work in the Industries" based upon a survey of some twenty-seven establishments which provided dental service for their employees. Since that date the work has been largely expanded, though figures representative of the present stage of development are not at this time available. This activity has developed to a point where it could well profit by organization with a view to bringing together for conference and mutual improvement the whole body of dental surgeons who are specializing in this field.

Such an organization in medicine is already actively at work within medical lines. The American Association of Industrial Physicians and Surgeons was organized at Detroit in June 1916 in conjunction with the American Medical Association. One hundred and fifty members were in attendance. Its objects are to interest industrial physicians in a common purpose to put industrial medicine and surgery on a higher plane and to interest the general medical profession in the activities of industrial physicians and surgeons. At the 1917 New York meeting of the A. M. A. the membership of the American Association of Industrial Physicians and Surgeons had increased to three hundred and fifty. Its next meeting will be held in Chicago June 10th. In view of the common purpose involved it would seem desirable and practical to form a society of Industrial Dental Surgeons in affiliation with the general medical organization, dealing as it does with the broad question of the physical well-being of industrial employees.

To further the plan of organization herein suggested, the DENTAL COSMOS will be glad to receive from its readers the names and addresses of industrial concerns within their knowledge which have already provided dental treatment for employees as a feature of their welfare service, and the names and addresses of dental practitioners who are engaged in industrial welfare work.

As the public service relations of dentistry are developing so rapidly in such a variety of ways, it would seem to indicate the desirability of creating in our National Dental Association a division dealing with the Public Service Relations of Dentistry, having its subdivisions of military, school, eleemosynary, and industrial dental service. The present sectional division of National Dental Association work has outgrown its practical usefulness as the profession itself has outgrown its swaddling-clothes.

A Correction.

IN the signature of Dr. C. W. RATCHEFF of Chicago to his interesting communication, "A Case of Tooth Gemination," published in our April issue, page 300, his name was inadvertently printed "BATCHEFF."

BIBLIOGRAPHICAL

A HANDBOOK OF ANTISEPTICS. By HENRY DRYSDALE DAKIN, D.Sc., F.I.C., F.R.S., and EDWARD KELLOGG DUNHAM, M.D., Emeritus Professor of Pathology, University and Bellevue Hospital Medical College. Pp. 129. Cloth, price \$1.25. New York: The Macmillan Co. 1917.

In this little volume of 129 pages the authors present in a very convenient form a rehearsal of the most approved chemical antiseptics as they are employed in the present war. In a general discussion of the members of the aromatic series (*e.g.* phenol), the heavy metals, aniline dyes, atomic oxygen (hydrogen peroxid), boric acid, iodine, etc., the authors present a more intimate study of the various members of the chlorin group. Of these, the chloramins receive

the bulk of attention, as it is here that the authors have carried out their important research work. Of all the known chemical disinfectants, chlorin, freshly prepared and in the presence of moisture and a suitable temperature, possesses the greatest known germicidal power. Chlorin forms the active constituent of Labarraque's solution, Javelle water, antiformin (dental radicin), electrozone, (or dental meditrina), and of the antiseptic solution so successfully employed at present in the English and French war hospitals according to Dakin's formula by the Carrel method.

The great success obtained with Dakin's solution rests primarily upon the fact that a fresh preparation according to a specific method is employed, which, while acting deleteriously on the germs, does little harm to the tissue cells, as it

is a non-irritating isotonic wound antiseptic. All of these solutions have sporadically come to prominence in the past. While the laboratory reports, as far as the germicidal power of these solutions is concerned, appear to be highly satisfactory, the results of their practical application are not altogether so. It should be borne in mind that most of these preparations are irritating, and that chlorin solutions are labile compounds. All of these enumerated solutions lose their activity within a week or two, hence the disappointing results when commercial stock preparations are employed.

To overcome the difficulties encountered in the utilization of the unstable aqueous solutions of chlorin, Dakin devised chloramin-T, and finally dichloramin-T. The latter term is the abbreviated name of toluene-parasulfon-dichloramin. This compound forms a comparatively stable solution with certain chlorinated oils, and readily parts with its chlorin content in the presence of wound secretions.

It is to be regretted that the writers furnish so little information regarding the practical application of this new compound in hospital work. As the book is primarily intended for the use of physicians and surgeons, nothing is said regarding the use of dichloramin-T for the purpose of sterilizing infected root-canals and other dental purposes. It is here, however, that this new chlorin compound will achieve its greatest triumphs in the practice of dentistry, and the reviewer, from an extended clinical experience with it, predicts for dichloramin-T a most important place in the armamentarium of the dental practitioner.

[INTER-ALLIED DENTAL CONGRESS.]
CONGRÈS DENTAIRE INTERALLIÉS.
Tenu à l'Ecole Dentaire de Paris du
10 au 13 Novembre 1916. Comptes
rendus publiés par Georges Villain,
Secrétaire-général. Tomes I, II.
Paris, 1917.

The subject matter of the reports is almost entirely devoted to the treatment and physiology of fractures of the mandible and the maxilla.

All the authors agree that it is essential to reduce the deformity and insert an appliance as soon after the injury as possible. On account of the injury of the soft tissues the appliances will vary. The second essential point is frequent irrigation of the entire mouth and wound under pressure.

Throughout the entire series of reports one is impressed with the number of appliances used for correcting the secondary contractures and deformities. It is especially noted that the correct primary appliances and treatment will greatly diminish the number of these deformities. There is no one method that is applicable to all cases, but the ingenious methods reported are very admirably described and should be more generally known. While it would seem unnecessary, it is noted in the reports that after bony union has occurred it is not advisable to attempt any method of correction without first dividing the bone.

An interesting point is that practically all the work has been developed upon the fundamental principles laid down by Claude Martin in his work. The cicatricial contracture of soft tissues is shown to be admirably treated by continuous pressure and massage.

These reports are the most complete it has been the reviewer's pleasure to

see. The volume is exceptionally well and fully illustrated.

Books Received.

Books received are acknowledged in this column, and such acknowledgment must be regarded as a sufficient return for the courtesy of the sender. Selections will be made for review in the interests of our readers and as space permits.

"Practical Dietetics with Reference to Diet in Health and Disease." By ALIDA FRANCES PATTEE, Graduate of Department of Household Arts, State Normal School, Framingham, Mass. Late Instructor in Dietetics, Bellevue Training-school for Nurses, Bellevue Hospital, New York City; former Instructor at Mount Sinai, Hahnemann, and the Flower Hospital Training-schools for Nurses, New York City; Lakeside, St. Mary's, Trinity, and Wisconsin Training-schools for Nurses, Milwaukee, Wis.; St. Joseph's Hospital, Chicago, Ill.; St. Vincent de Paul Hospital, Brockville, Ont., Canada. Eleventh Edition, revised and enlarged. Price \$1.75. Mount Vernon, New York: A. F. Pattee, 1917.

"Dental Electro-Therapeutics." By ERNEST STURRIDGE, L.D.S.Eng., D.D.S., Fellow of the Royal Society of Medicine, Member of the British Dental Association, of the British Society for the Study of Orthodontics, of the American Dental Society of Europe; contributor on Dental Electro-Therapeutics in "The Science and Practice of Dental Surgery," on Ionic Medication in Prinz' "Dental Materia Medica and Therapeutics." Second Edition, thoroughly revised. With 164 engravings. Philadelphia and New York: Lea & Febiger, 1918. Price \$2.75.

"Elementary and Dental Radiography." By HOWARD RILEY RAPER, D.D.S., Professor of Roentgenology, Operative Technic, Materia Medica and Therapeutics at the Indiana Dental College, Indianapolis. Past Dental Surgeon to the Indiana School for Feeble-minded Youth. Member of the American Institute of Dental Teachers, of local, state, and National dental societies, of the First District Dental Society of the State of New York, and the Western Roentgen Ray Society; Associate Fellow A. M. A., Section on Stomatology.

With over 500 illustrations. Second Edition. Adopted as a Textbook by the National Association of Dental Faculties. New York: Consolidated Dental Mfg. Co. London: Claudius Ash, Sons & Co., Ltd. Price \$7.00.

"Injuries of the Face and Jaw and Their Repair, and the Treatment of Fractured Jaws." By P. MARTINIER, Professor in the Dental School of Paris, Dentist to the Seine Asylums, Hon. Director Dental School of Paris, and Dr. G. LEMERLE, Professor in the Dental School of Paris, Dentist to the Hospitals. Translated by H. LAWSON WHALE, M.D., F.R.C.S., Captain R.A.M.C., T. (formerly Capt. I.M.S.), the Oral Dep't, No. 83 Gen. Hospital, Br.E.F.; Visiting Surg. to the Throat, Nose, and Ear Dep't, County of London War Hospital, Epsom; Laryngologist to the London Temperance Hospital and Hampstead General Hospital. New York: Wm. Wood & Co., 1917.

"Technique and Scope of Cast Gold and Porcelain Inlays." With a Chapter on Endocrinodontia, or the Ductless Glands—Their Expression in the Human Mouth. By HERMAN E. S. CHAYES, D.D.S., New York City. With 372 illustrations. St. Louis: C. V. Mosby Co., 1918. Price \$7.00.

"Gould and Pyle's Pocket Cyclopedia of Medicine and Surgery." Based upon the Second Edition of Gould and Pyle's Cyclopedia of Practical Medicine and Surgery. Second Edition, revised, enlarged, and edited by R. J. E. SCOTT, M.A., B.C.L., M.D., New York, formerly Attending Physician to the Demilt Dispensary and the Bellevue Dispensary: Author of "The State Board Examination Series." Editor of "Witthaus' Essentials of Chemistry and Toxicology" and "Hughes' Practice of Medicine," etc. Philadelphia: P. Blakiston's Son & Co. Price \$1.25.

"Health by Instruction." An Effort in Favor of a Biologic Teaching. By LUIS SUBIRANA, Cirujano-Dentista, Professor in the Dental School of Madrid. English Translation by FRANK J. YOUNGER, D.D.S. Madrid: Sociedad de Artes Graficas, Fuencarral, 137. 1918. Price \$1.00.

The title of this book does not properly indicate its contents. It is in reality an interesting and valuable expression of the author's views on the subject of education in hygiene.

REVIEW OF CURRENT DENTAL LITERATURE

[*British Dental Journal*, December 15, 1917.]

Some Observations on the Replantation and Transplantation of Teeth, with Special Reference to the Patho-histology of the Tissues of Attachment. By F. C. WILKINSON.

Recent interest in this old procedure has been signalized by the work of Marshall (see *DENTAL COSMOS*, 1918, p. 169) and Chiavaro (*ibid.* p. 261). Wilkinson prefaces this study with a concise historical orientation on the matter which is well worth reading by anyone interested. His original investigations on this subject were conducted with the object in view of establishing the method of fixation of replanted teeth to the surrounding tissue, with special reference to the function of the periosteum in these cases, and also to study the process of absorption which takes place. For this purpose monkeys (species not given) were taken as being the highest form of animal easily obtainable. Similar teeth were extracted from each side of the mouth, and after several days' interval were replanted under identical conditions, with the exception that in one side the tooth was completely stripped of its periosteum, and the other was left intact. After these teeth had been in position for about two months that specimen was obtained and the sections made. The technique of the operation is given in detail.

Under low power of the microscope these sections show that absorption of the roots has begun in both cases, but it is notable that the root upon which the periosteum had been left shows more absorption than the root from which it had been stripped. In fact, except for the slightly greater amount of absorption in one case than in the other, it is quite impossible microscopically otherwise to distinguish between the two roots replanted,

the one with the periosteum left intact, and the other from which it has been removed. In the sections it is to be noticed that absorption is not equally distributed over the roots. In places the cementum seems to remain intact, and no evidence of absorption can be found, while in other parts it is proceeding rapidly. Wilkinson suggests that this condition is due to asepsis not being perfectly maintained, a very difficult proposition when operating in the mouth and with bony tissue.

The alveolus shows little sign of any absorptive process, but in some places new bone has grown out from the alveolus and fused to the cementum.

In summary: (1) The presence or absence of periodontal ligament upon a replanted tooth has no appreciable effect upon the mode of attachment.

(2) Absorption seems to take place to a greater or less extent in all cases, the immediate cause being large multinucleated cells, osteoclasts.

(3) Three kinds of attachment can be differentiated—(a) in certain portions of the root the alveolar bone is found directly united to the root; this osseous union probably occurs in places where the root and alveolar bone came in close apposition; (b) in other places attachment is obtained by ordinary scar tissue (this is the preponderating method of attachment); (c) in a small part attachment may be by long connective tissue fibers markedly simulating the normal periodontal ligament. At such places there is no absorption of the root. The establishing of this effort at a true regeneration is one of the most interesting points of the author's observations. This tissue has nothing to do with retained periodontal ligament on the replanted root. Under ideal conditions, which Wilkinson is unable to define, it might be possible to obtain such a form of attachment

throughout, which presumably would be as permanent as in the normal condition.

In this connection a letter from C. Lotinga in the *British Dental Journal* for January 15, 1918, p. 52, is of practical interest. A right maxillary second incisor with a history of caries and death of the pulp, root-canal treatment, and subsequent abscess, was extracted. Tissue paper, soaked in phenol, was wrapped around the root, its crown was cut off, and its hypercementosed apex resected. The periodontal ligament was stripped off *in toto*. A Richmond crown was fitted and a Dale's porcelain inlay was placed in the apex. The thus remodeled tooth was replanted in its socket just six hours after extraction. A splint was kept on for six weeks. The tooth remained perfectly comfortable for sixteen and a half years, when it was fractured by accident. Two-thirds of the root were left in position, from which to date—an additional period of three years—there has been no trouble.

Kells, in *Dental Items of Interest*, February 1918, records a case of replantation. At the present time, more than nine years since the operation, the tooth is apparently in perfect condition.

[*Journal of the Medical Association of Georgia*, Augusta, October 1917.]

Tumors of the Gums. BY J. L. CAMPBELL.
[*Surgery, Gynecology, and Obstetrics*, Chicago, December 1917.]

Giant-cell Epulis of the Upper Jaw. BY FRANCIS REDER.

[*Revista Odontologica*, Buenos Aires, January 1918.]

The Pathological Anatomy of Epulides.
BY R. ERAUSQUIN.

The first two papers deal with case histories and surgical intervention. The last paper is a rather pretentious survey of the patho-histology of these growths.

Campbell reports two cases. One was an angio-fibroma of the gum in a white girl of sixteen years. The family and personal history was negative. About seven years previously there was first noticed a lump, about the size of a pea, on the labial surface of the upper left gum in front of the first molar. It gave no pain, and grew slowly until about one year ago, when it began to increase rapidly and bleed rather freely. The general

health had been good until quite recently, when the patient began to lose flesh and feel ill. On examination was seen the pointed end of a reddish tumor protruding from between the lips and extending distal to the faucial pillars. It is raised above the teeth so that she cannot close her mouth. The teeth are irregular, decayed, broken, and very black. A cherry-red nevus is around the corner of the mouth. The tumor does not involve the cheek, but pushes it outward. The Wassermann was 4 plus. The blood showed 3 million reds, 7000 whites, and hemoglobin below 50 per cent.

Under ether anesthesia, the periphery of the entire mass was well infiltrated with a 0.25 per cent. novocain and 12 per cent. 1:1000 adrenalin in physiologic salt solution. There was very little hemorrhage. Recovery was complete. Microscopically the deep portion of the growth was fibrous, while its anterior and superficial parts were angiomatic. There was no indication of malignance.

The second case was that of a colored woman, age sixty. The family and personal history was negative. About six years ago a small lump was first noticed on the labial surface of the lower right gum between the second incisor and the canine. There was no pain until about two weeks ago, when the growth began to throb as if it would burst. It was about the size and shape of a white-oak acorn, firm, and the color of the gum. It had separated the teeth between which it grew, and apparently had a thick pedicle.

Under local anesthesia the adjoining teeth were extracted, and a V-shaped piece of the gum with the tumor was cut away and the margin of the alveolus pinched off to insure complete removal. Microscopically the growth was a pure fibroma.

Campbell's article is illustrated with three portraits, not of special value.

The original part of Reder's paper is a case report. Four illustrative portraits of the "before and after" variety are introduced. The case was that of a woman, age fifty-two. Several teeth in the maxilla were loosened by a hen flying into her face. About one month later, a bad persistent toothache began. A tooth was extracted. There was prompt relief. Two weeks later she noticed a swelling on the upper gum near the right canine.

This was diagnosed as a "gumboil" by a physician. It was lanced, but slowly continued to grow, although without pain. About six months later the growth was so large as to force her to see a physician. The tumor was then occupying the greater part of the gum of the upper jaw. Most of the teeth were very loose, and either dropped out or were easily extracted. The mass was cut away by the physician within one month. After that the area was freely cauterized with silver nitrate. Within two weeks the growth had returned, and was increasing rapidly.

Finally the case was presented to Reder, about five or six months after the growth had first been noticed. Examination showed a venous-colored, spongy mass, about the size of a small tangerine, attached to the alveolar border of the upper jaw. Projections and irregularities were on its surface, and it extended on to the hard palate, protruding under the upper lip, which was pushed upward and outward. The mucosa of the alveolus was thickened, somewhat soft, and very red. The teeth of the maxilla were all missing. The sulcus between the teeth and the alveolar border was normal. There was no fetid discharge.

Operation. Incision was made through the mucosa, quite free of the tumor. With chisel, the whole of the alveolar border of the maxilla was removed. Bleeding was very free, but readily controllable under pressure. Recovery was uneventful. Four months after the operation the patient was fitted with a "palate plate with teeth." After the lapse of three years there was still no sign of recurrence.

Erausquin's article is illustrated by four-teen photomicrographs. His study is based upon ten specimens, the clinical histories of none of which are given. These may be grouped into three principal types—(1) giant-cell sarcoma with an osseous-fibrous skeleton, (2) fibroma durum or infiltrated osteo-fibroma, and (3) fibro-lymphoma or soft fibroma. The conclusions of his histological study are as follows:

(1) Possibly the giant-cell sarcomata arise from the dento-alveolar periosteum, previously irritated.

(2) The osteo-fibromata probably originate in the alveolar bone and its periosteum, although these tissues do not appear to par-

ticipate directly in the production of the fibro-lymphomata, which quite possibly may come from the chronically inflamed corium of the gum.

(3) The indisputable benignity of these neoplasms, even those of the first type, is easily explainable when we remember the small cellular polymorphism of the giant-cell sarcomata, their good fibrous envelope, and the great development attained by their osteo-fibrous framework.

(4) For the present, in the extirpation of every epulis, except the fibro-lymphomata, it seems indispensable to insist on the extraction of the corresponding tooth or root, the resection of the alveolus, and the galvano- or thermo-cauterization of the bony surface when the growth is first discovered, in order to guarantee as far as possible against return, which is so frequent in this class of tumors.

Primary Syphilis of the Gums. BY ACHILLE BREDÀ.

This is a report based on three cases. The location is decidedly rarer than that of the lips and tongue. The sore appeared on the labial aspect of the gums: was painless although rapidly growing. There was the usual glandular involvement and subsequent rash. This condition has to be distinguished from swelling due to traumatic periosteitis and fibroma. The glandular involvement leads to confusion with neoplasms. The syphilitic lesion is characterized by its history of short duration and the fact that it is localized to the mucous membrane. The lesion is not usually large, is sharply demarcated, and of semilunar outline. Elevated, pedunculated, lobulated, or massive swellings are not likely to be syphilitic.

Alcohol Sterilization. BY J. CHRISTIANSEN.

Christiansen's extensive research seems to show that propyl alcohol has numerous advantages over ordinary alcohol for sterilization. Apparently this alcohol makes its way rapidly into the cells when the superficial tension of about 0.4 is reached. Once inside the cells, the alcohol induces a kind of fixa-

tion: *i.e.* in combination with the salt present in the bacteria it produces an irreversible precipitation of the protoplasm which signifies the death of the bacterium. Higher concentrations of alcohol do not have this effect, but merely tend to desiccate the organisms. The action of propyl alcohol in this dilution compares favorably with that of iodine, phenol, and other powerful disinfectants. The author urges the general use of *n*-propyl alcohol as a disinfectant for skin and wounds. When pure it mixes freely with water. Mixed with three times as much water, the superficial tension is 0.4. Inasmuch as ethyl alcohol is used so generally in dental practice for sterilization, it might be desirable to compare its efficiency and applicability under conditions of practice with that of *n*-propyl alcohol.

Retention of Full Dentures. BY RUPERT E. HALL.

The principles which Hall enunciates are, as he himself states, those of Wilson, as given at page 168, February 1918 DENTAL COSMOS. Areal contact, peripheral bearing of the base-plate, and extension upon yieldable tissues are sought, to utilize to the utmost the physical forces of adhesion, cohesion, and atmospheric pressure in the retention of artificial dentures.

Recognition of these principles is especially called for in that type of edentulous jaws with poorly defined or excessively absorbed ridges, marked distortion or loss of facial contour, and abnormal or subnormal quantity and tone of the underlying and adjacent tissues.

To secure retention the taking of a perfect impression is the basic essential. Hall for this purpose employs an impression-tray compound, with a thin mix or two of plaster. In trimming the impression-tray-compound tray, advantage should be taken of the canine fossa, of the area just posterior to the molar process, and of the spaces on each side of the frenum of the tongue, so as to secure the maximum areal contact. Special attention is given to the margin of the impression directed toward the soft palate. Proper compression of the soft tissues is secured by a tracing of impression compound along this margin to dam back the plaster.

After taking the impression, the second

factor in insuring retention is intelligent attention to the anatomical occlusion and articulation. In fact, to Hall, anatomical occlusion and articulation mean the arrangement of the artificial teeth so as to secure greater efficiency, and their aid in the retention of the denture. To secure these aims Hall insists that the teeth should have deep angular cusps, so mutually and purposively arranged that they shall guide the masticatory movements in a way as nearly approximating normal as possible. This is reminiscent of the inclined planes of the orthodontist. None of the teeth at present on the market satisfactorily meet this requirement.

A further factor in securing these aims is the establishing of the proper tooth length and bite. In this Hall varies from the usual teaching. Normally, when the teeth are occluded the lips are compressed and much shortened; conversely, when the lips are compressed and shortened in the edentulous patient, this position will more nearly give us the true tooth length and bite. Another detail in line with this which Hall advocates is that in articulating the teeth the incisors should be arranged to overlap (as normally) and ground to establish perfect opposing articulating edges and planes.

Case of Chronic Nephritis: Uremia; Severe Hemorrhage from Gums. BY W. ASHLEY COOPER.

The patient, a woman of thirty-three years, was admitted to the hospital for edema of the legs, albuminuria, and hemorrhage from the gums. At the age of four she had had scarlet fever complicated by nephritis, from which time until admission to hospital she had only complained of bilious attacks. Her mouth was in a very septic condition; her breath was very offensive, and blood could be seen oozing freely from the gingival margins. The gums were very anemic, and the patient had pyorrhea. Much tartar was present, which was removed. Various hemostatics were applied locally, but with no permanent effect. The coagulation time of the blood was markedly prolonged. Death ensued.

This case history is of interest in the light of Miner's article on the "Influence of General Health on Oral Tissue," in the March 1918 DENTAL COSMOS.

March 1918.]

**The Relative Efficiency of Medicaments
for the Sterilization of Tooth Structures.** BY M. M. BROOKS AND W. A. PRICE.

This paper is limited to the sterilization of infected dentin and cementum as involved in root-canal infection following the death of the dental pulp. A very interesting historical survey serves to orient the reader in the problem, and furnishes a valuable bibliography.

The authors recognize that the following structures and conditions exist as important factors: (1) The root-canal to which the infection has access, and through which the infection can reach the dentin; (2) the dentin with its tubuli; (3) through the foramen or foramina the infection can reach the cementum, which probably can also be infected from the dentin; (4) the periapical tissues, which constitute not only the pabulum but also a locked area which may contain an infected culture medium, which may reinfect the cementum and dentin and the root-canal contents.

The experiments have been arranged in the following order: (1) A study of the ability of the medicaments to sterilize dentin and cementum under the most ideal conditions, irrespective of compatibility with clinical conditions; (2) the study of the ability of the medicaments to even retain the sterility of a medicated dressing when placed in an infected root-canal without the influence of a periapical infection; (3) the influence of a periapical infection upon these last-named conditions; (4) the ability of medicaments placed within the root-canal to sterilize infected dentin and cementum while these tissues are surrounded by a periapical infection, including a study of the areas of these structures that are most readily sterilized; (5) a study of the time factor, and (6) a study of silver-ammonium-formalin and Dakin solutions.

The results of the first series of experiments show that even under ideal conditions, where the medicament bathes both the inner and the outer surfaces of the infected tooth structure, and even where the mass of the medicament is relatively large and without

compatibility for the surrounding tissues, the dentin and cementum were not disinfected except with a few medicaments, namely, formalin in all strengths (in the protocols this is given in percentages of formaldehyd—40, 30, 20, 10, 5, and 1) and chlorphenol. The great majority of results were negative and in direct contradiction to the general teachings and expectations in current dental practice. It is very difficult to destroy bacteria growing in dentin and cementum.

The conclusions to the second series of experiments are that the most radical disinfectant is dichloramin-T. This medicament in a concentration of 15 per cent. as used in these experiments gave 100 per cent. efficiency in all treatments, but also produced irritation of living tissue. A further observation on the lowest percentage needed for root-canal sterilization and the amount of time for the production of this condition will be continued. This drug may, in dilute solution of 1 per cent. or less, be both safe and efficient, but it is one of the most painful and destructive medicaments tried in practical cases. The members of the profession are warned never to place the 15 per cent. or even 5 per cent. solution of dichloramin-T in eucalyptol, its solvent, in any tooth or on tissues. (However, the newer solvent, chlorcosane, is devoid of this irritative effect.)

The third series of experiments shows that under the conditions specified above, the medicaments used—Buckley's phenol compound, dichloramin-T 15 per cent., formocresol, iodoform, iodin U. S. P., formalin U. S. P., phenol U. S. P., and oil of cloves 50 per cent.—are not ideal disinfectants. The interpretation of this experiment is probably that the penetration of the disinfectant is not sufficient to reach the remote and minute recesses of the tubuli. To find some disinfectant or method that will meet this requirement is the subject of the remaining experiments, although these are not yet completed.

The fourth series emphasizes that the efficiency of a medicament to sterilize *all* tooth structures should be the criterion of a disinfectant.

Experiments upon Howe's silver nitrate-ammonia-formalin method (see DENTAL COSMOS for September 1917) incline the authors to believe that a perfected technique will produce sterilization of the tooth structures

which are reached by the medicament in so short a time as ten minutes.

The experiments on Dakin's chlorazene and dichloramin-T give much encouragement for their use. They are, however, painful and destructive in over 0.5 per cent. strength. It must be remembered that this conclusion was drawn when eucalyptol was the solvent; the solvent chlorcosane eliminates this irritative action, so that percentages of dichloramin-T of over 6 per cent. may be used.

Among the general summary the points which are of special interest are—(1) The efficiency of a root treatment is greater a few hours after it has been placed in the tooth than after several days' or even one day's time; (2) all areas of cementum and dentin are difficult to sterilize, as well as tend to reinfection when the medicated root dressing is left more than a few hours; (3) the medicaments that are most efficient, namely, silver nitrate and formalin, are very objectionable, the former by its discoloration and the latter by its destructive and irritating properties, except when used very dilute and for a short time, and then quite efficiently. The signification of this last cryptic phrase is revealed in *Oral Health* for April 1918, by Price, in a description of the method of Cameron of Girard College, Philadelphia, for the sterilization of root-canals, which Price characterizes as superior in results to any other current method. Put 4 per cent. solution of formalin into the accumulated debris and use it as a solvent for washing out the pulp chamber and canals, but not undertaking to put any of it through or to the apex. Follow this with a 2 per cent. solution of formalin. The canals are not flooded, but merely moistened with this solution. Place a hot wire into the canals, and when the solution is raised in temperature to about 120°, which will not be particularly unpleasant to the patient, formaldehyd gas is given off rapidly and profusely, and passes into the structures of the tooth. Teeth treated in this way show a very high percentage of efficiency, and the laboratory tests of Price and collaborators have confirmed it as more efficient than the methods used in the past. All is done at one short sitting, and the canals are immediately filled. In this way the irritative after-effect of formalin is quite obviated.

[*American Journal of Clinical Medicine*,
Chicago, April 1918.]

Causes of Bad Breath. BY C. W. CANAN.

Bad breath may be owing either to local causes or to systemic disease. Among the causes that are local there is dental caries; however, bad mouth odor more often is a consequence of decaying food particles adhering to the teeth. The breath is very characteristic in pyorrhea alveolaris. Bad breath may arise from diseased conditions of the nasal cavity; especially so in chronic hypertrophic rhinitis. It is very fetid in gangrenous stomatitis, and sickening in necrosis of the jaw. Diseases of the tonsils, larynx, and pharynx disagreeably influence the breath. In follicular tonsillitis and pharyngitis, the odor is due to decomposition of the secretions and particles of food filling the follicles, and is like that of fecal matter, while that of diphtheria is suggestive of putrefaction. Canan does not refer to the breath in cases of Vincent's infection of the oral mucosa, which is so characteristic as to be almost pathognostic.

Among the systemic diseases in which the breath odor is adversely modified, Canan mentions diabetes mellitus, glaucoma, pyemia, chronic alcoholism, gastric and intestinal disturbances, nasal and oral localizations of syphilitic infection, aphthous stomatitis, uremia, gastric and hepatic carcinoma, pulmonary abscess, and chronic bronchorrhea. In addition to the above it is known that fits of anger or great excitement may and often do produce fetid breath; the breath of some women is always offensive during their menstrual periods; there are certain individuals, seemingly in perfect health, who have a bad-smelling breath all the time, usually attributable to faulty elimination.

Canan briefly considers the treatment. He makes the serious mistake of outlining the treatment in cases where the cause is localized in the oral cavity, and inferring that the general practitioner is able to deal effectively with such cases. Where the physician by elimination has located the cause of bad breath in the oral cavity, there remains nothing legitimate for him to do but to refer the patient to the dentist. The converse of this is fully appreciated by the dentist.

The particular paragraph of the treatment

which may be of dental interest follows: In all ulcerative conditions of the mouth and fauces, a mouthwash or gargle or spray should be prescribed containing chlorazene in physiologic sodium chlorid solution. Another good treatment is to have the mouth rinsed with a dilution of specific medicine of thuja. Also ulcers should be painted with this thuja extract of full strength.

[*Journal of the American Medical Association*, April 20, 1918.]

The Transplantation of Bone. By W. E. GALLIE AND D. E. ROBERTSON.

This article is a very sensible and well-illustrated one, of some interest to dentists from the standpoint of war surgery. The employment of this method in an operation on the jaw sequent to fracture with loss of substance is described, and also as applied in general in wounds of the face. They conclude with a statement of the principles that should govern the science of bone-grafting. It must be remembered that a so-called living autogenous bone-graft is alive only by virtue of the osteoblasts that are free on its surfaces and in the mouths of the Haversian canals. All the rest of the graft dies, and is absorbed. It owes its value in bridging gaps and in encouraging union of ununited fractures to the fact that during the process of its absorption the osteoblasts which invade it from its own surfaces and from the neighboring bones build up new bone to take the place of that which is absorbed, so that ultimately the break in the continuity of the injured bone is bridged by new and healthy bone. This established fact indicates at once the necessity for perfect contact of the graft with fresh, healthy bone in the fragments, and shows the reason for extending the graft well beyond the sclerosed extremities. It also shows the importance of using, as a graft, bone from which the periosteal and endosteal surfaces have not been removed, and it is on these surfaces that the greatest number of osteoblasts is to be found. For the same reason the graft should be made from bone which is as porous as the requirements of the case, in relation to strength, will allow. Hence the value of the rib as a graft, particularly if it has been opened up so that the osteoblasts of its interior can obtain the necessary supply of lymph. After the prin-

cipal graft has been inserted as many small pieces as possible should be packed around it, the fragmentation increasing the surface area exposed, and hence increasing the number of surviving osteoblasts. In those cases in which the introduction of living osteoblasts is not an essential feature of the operation, the value of boiled bone must not be overlooked, as it possesses many of the virtues of the autogenous graft without some of its disadvantages.

[*Journal of the American Medical Association*, January 5, 1918.]

The Disinfection of *Pneumococcus-carriers*. By JOHN A. KOLMER AND EDWARD STEINFELD.

In the DENTAL COSMOS for December 1916, p. 1425, attention was called to the marked germicidal action of ethyl-hydrocuprein upon pneumococci. At that time it was suggested that this drug might be of some benefit in the treatment of pyorrhea alveolaris, in view of the fact that pneumococci are found in pyorrhetic pockets along with the closely related streptococci. The report now to be considered further enhances the desirability of putting this proposition to test. The authors have studied the disinfection of sputum and the mouth with solutions of various cinchonics in a menstruum of liquor thymolis. Their experiments demonstrate that the latter solution alone in dilution of from 1:4 to 1:10 possesses some germicidal activity for pneumococci, and aids in disguising the bitter taste of cinchona compounds. This problem has been mainly approached from the laboratory side, employing both normal mouth secretions harboring type 4 pneumococci and the sputum of pneumonia convalescents harboring type 1 pneumococci. The pneumococcal activity of the disinfectant under study was largely determined by mouse inoculation.

The systematic use of ethyl-hydrocuprein hydrochlorid (1:10,000) in a 1:10 dilution of liquor thymolis, twice or more daily, is not dangerous from the standpoint of toxicity due to swallowing portions of the drug, is not unpleasant (bitter taste readily removed by rinsing mouth with plain water), and may aid in ridding the mouth of virulent pneumococci. Similar solutions, incorporated in a dental cream, may be used for cleansing the teeth. For washing the mouth or gargling,

a solution is conveniently prepared after the following formula:

| | gm. or cc. |
|---------------------------------|---------------|
| Ethyl-hydrocuprein hydrochlorid | |
| or quinin bisulfate, | 0.005 |
| Liquor thymolis, | 5.0 |
| Distilled water, | q. s. ad 50.0 |

[*Bulletin of the Canadian Army Medical Corps*, Ottawa, March 1918.]

Infectious Ulcero-membranous Stomatitis and Gingivitis. BY — BOWMAN.

Clinical and bacteriological examination was made of 1000 men in camp to learn (1) the number of men who cleaned their teeth carefully and the number who did not; (2) the number of men in each group showing Vincent's organisms present in significant number; and (3) the number of cases of clinically infectious gingivitis in each of these groups. There were 816 men with clean teeth; 314 (38.4 per cent.) showed Vincent's organisms present, but very few in number; 20 (6.4 per cent.) showed large numbers of spirochetes and fusiform bacilli, and were clinically positive cases.

Of the 1000 men 184 showed unclean teeth; 139 (75.6 per cent.) of these showed a few Vincent's organisms; 59 (32 per cent.) showed the organisms present in large number, and these cases were all clinically positive.

Bowman's conclusion is that not only are Vincent's organisms much more prevalent in mouths not cared for, but clinically infectious gingivitis is also much more prevalent, and corresponds practically with the bacteriological findings.

[*Journal of the American Medical Association*, April 27, 1918.]

Gonococcus Infection of the Mucous Membrane of the Oral Cavity. BY J. M. MAYHEW.

This is the detailed history of a single case. The patient denied venereal disease or recent exposure of any kind. The infection was apparent within twenty-four hours after he had had his teeth cleaned by a dentist. The whole picture presented a most severe type of mouth infection. Bacteriological examination showed an organism, identified with the diplococcus of Neisser.

The patient was sent to the hospital, isolated, and treated with a mouthwash of a saturated solution of thymol. The mouth and throat were swabbed daily with a 2 per cent. silver nitrate solution. Forty-eight hours after institution of treatment, the exudate began to disappear, leaving a raw, bleeding surface. At no time was there any odor from the mouth. Smears were negative on the twelfth day. Cultures were also negative.

PERISCOPE

Paper Points in Cleaning Root-canals.

—Paper points may be passed along the canals with less danger of forcing dead material through the apex of the root than it would be possible to do with cotton wound upon a broach. Paper points also absorb moisture much more quickly and thoroughly, and give a better idea of the size and length of the canals.—D. H. SQUIRE, *Journ. N. D. A.*

Polishing Material for Dentures.—When the denture has been filed and dressed with the scrapers, the surface may be smoothed very rapidly by the use of equal parts of pumice, emery, and silex of medium fine grit.

By uniting these powders with equal parts of beeswax and hard oil the spattering and dust will be avoided and polishing will be a comparatively clean proceeding.—*Pacific Dental Gazette*.

Opening of the Pulp Chamber in Tender or Sore Teeth.

—In caring for these teeth, frequently the patient cannot stand the pressure of instrumentation necessary to open the pulp chamber. To overcome this to a large extent I would advise the placing of a ligature of Cutter's silk around the neck of the tooth, and have the patient bring traction on the tooth, allowing him to pull as

hard as the pressure that is being exerted by the bur. In the case of the mandibular teeth the ligature may be placed over the head in order to pull up on these teeth. Another method that serves nicely is to place some modeling compound between the teeth to hold them apart, and then extend two wings of this material laterally, molding it into the interproximal spaces. When this splint is cooled and in place it will support the tender tooth during the operation, reducing pain to a large extent.—F. H. FRAHM, *Pacific Dental Gazette*.

Preparing the Stump for a Crown.—When preparing the stump of a bicuspid or molar for a crown by grinding with stones and vulcarbo disks, angles are made that are very difficult to reduce. This trouble can very largely be overcome by the use of cloth and paper disks treated with a little vaselin or lard oil to keep them from getting wet and useless. These disks can be compelled to curve, and will cut only on one side; also they are not nearly so liable to injure the soft tissues.—*Pacific Dental Gazette*.

Preparation of the Mouth Cavity Previous to Dental Operations.—In preparing the mouth cavity previous to a dental operation it is essential that the field of operation be as clean and free from bacteria as possible. In order to get a clean field the following procedures are suggested: (1) Mechanical cleansing of the teeth in the office before operating. (2) The use of a good spray of mouth-wash. (3) Applying only a well-disinfected rubber dam, the tooth surface being disinfected before applying it as well as after.

If the above procedures are carried out one may be satisfied that he is operating in a clean but not a sterile field.—ADAH ROBERTA HOLMES, *Journ. Calif. State Dental Association*.

Root-canal Treatment a Specialty.—In view of our latest investigations and thoughts on this subject, there is little doubt that the treatment of pulpless teeth will soon become a well-recognized specialty. Many dentists are naturally unfitted for operations of this nature. As long as it is considered to be a duty of general practitioners they are forced to make an attempt to do what they realize they are not fitted for. If it were a well-recognized specialty, a large proportion of dentists would delightedly abandon such operations. The new standard of practice would receive a much earlier recognition if the subject were only discussed by such men as devote their time to the practice.—M. L. RHEIN, *Dental Items of Interest*.

Deaths from Cancer.—One woman out of seven and one man out of eleven, at the age of thirty-five, die of cancer. An average of 73,800 deaths occurred from cancer in the last ten years. In New York state in 1913, 9528 deaths were caused from cancer, nine times as many deaths as from typhoid fever. In twenty years the death-rate of cancer has increased 166.6 per cent., and if this death-rate continues for the next twenty years, it will be greater than the death-rate of consumption. Estimates indicate that from nine to twenty-six per cent. of all cancers are found on the tongue. Most of these cancers are on exposed surfaces where they may be discovered early, operated upon, and cured.—ALONZO M. NODINE, *Dental Summary*.

Vulcanite Tooth Replacement.—Several days ago the writer was shown a rather unique method of replacing a broken tooth in a vulcanite denture. After selecting a tooth of the right mold and shade, it is fitted into the recess of the broken tooth, with clearance for the pins, but without cutting the pink vulcanite. Then a horseshoe shaped loop several millimeters deep is cut in the vulcanite lingually to the tooth, leaving an island at the base sufficiently strong to resist a part of the strain that naturally will fall on this tooth. Now a small wire is twisted around the heads of the pins of the tooth, and fitted into the horseshoe-shaped groove. Lastly the tooth and wire are fastened and the case finished by sealing the repair work with zinc phosphate cement. This makes a rapid, easy repair that will last from six months to several years.—F. H. FRAHM, *Pacific Dental Gazette*.

The Mouth in a State of Health.—Were one to try to state the conditions that are essential to a state of health in the human mouth, they might be summarized under certain headings.

First would be placed occlusion. Why? Because occlusion not only is one of the most important factors in the maintenance of a state of health in the mouth, but we need to realize more than we do as a profession that occlusion is the mechanism through which normal function molds every anatomical detail of its entire structure. So during the whole period of development of the human mouth, occlusion, through the forces generated in function, is the means of development of the anatomical form and the most minute microscopical detail of every structure, and is one of the most powerful factors in the maintenance of health.—FREDERICK BOGUE NOYES, *Journ. Allied Dental Societies*.

The Basic Principle of Fixed Bridge Work.—Fixed bridge work which has proved to be the most successful and has rendered the fullest measure of service through years of vigorous usage is work which first of all has been made in accordance with the principles that it should be attached to or supported by one or more abutments when of straight alignment, and should receive additional attachment and support from one or more intervening abutments or piers when of curved alignment.

This law we believe to be based upon sound physiologic and mechanical principles; it is one which may be intelligently and definitely understood, and it specifically prohibits the employment of fixed bridge work in all cases where there is an insufficiency of anchorage teeth for proper support.

Fixed bridge work which has been constructed and applied outside of this principle is in some degree a failure from its inception, and if it is possible to compare failures, it is noticeable that the degree of failure seems to be in proportion to the extent of deviation from this principle.—A. J. BUSH, *Journ. N. D. A.*

Pyorrhea Alveolaris.—In the March number of the *New York State Journal of Medicine* are the papers and discussions presented in a symposium on Infections of the Cervical Lymph Nodes at a session of the annual meeting of the Medical Society of the State of New York, held at Utica, N. Y., in the spring of 1917. Pyorrhea alveolaris was a subject thoroughly presented. An important practical idea in the treatment of this disease was offered by George E. Barnes, M.D., of Herkimer, N. Y., who said—"An important matter is the *prevention* of infection of the nodes and of other parts of the body. Apart from those cases in which operative treatment is required there are many cases of pyorrhea alveolaris and a few cases of tonsillar crypt infection in which hygienic practice may be sufficient. This applies more particularly, of course, to adults. After brushing the teeth subsequent to each meal, about a teaspoonful of water is taken into the mouth, and flushed around while suction is made on all infected parts of the mouth and fauces. If the pyorrheal pockets and tonsillar crypts are not kept clean by this procedure, operative treatment must be further considered."

Removing Root-fillings.—In removing faulty root-fillings or artificial obstructions, chloroform under pressure should be employed at first for gutta-percha, using either a pledget of beeswax or unvulcanized rubber to get pressure for a few moments; then, with the canal flooded with chloroform, take a

fine smooth broach and endeavor to work down through or at the side of the gutta-percha, following the smooth broach with either a Donaldson barbed root-canal cleanser or a Kerr root-file of suitable size to remove the gutta-percha, repeating the process until the obstruction is passed. The canal then is washed with chloroform until the cotton is not stained by gutta-percha. In this washing, as well as the opening, every precaution is used not to force any of the contents of the canal through the apical end of the root.

Most root-canal pastes are soluble in acid, and when these are found, sulfuric acid should be used instead of the chloroform. When cement or gold has been used, the utmost caution must be employed in picking and cutting these out. As a cutting agent in these cases, I use the No. $\frac{1}{2}$ round bur, which must be employed with the most painstaking effort if trouble is to be avoided.—W. G. EBERSOLE, *Dental Summary*.

Reliefs in Artificial Dentures.—If a hard area is sufficiently pronounced so that it can be easily detected with the light touch of the finger, and the surrounding tissues and ridges are even slightly soft or yielding, it is well to place a relief of 20 to 22 gage over the most prominent part, and another thickness of 28 gage over the entire area of the bone.

It is always well to relieve more than one thinks is necessary, rather than too little, for the relief will serve the double purpose of a relief (or to eliminate leverage during masticating pressure) and an air-chamber, both of which are valuable if properly placed.

The writer does not believe in an air-chamber as it has generally been applied for retention, for the reason that, if it overlies soft tissue, it is only a question of a few days when the tissue will be drawn into it, and it will be of no value for the retention of the denture; and in many cases it will be the cause of hypertrophied tissue or a hard growth that will ultimately act as a fulcrum on which the plate will ride.

If the relief is placed over a hard bony area, there is, as a rule, no tissue that can be drawn into it, and if made deeper than the bony prominence, it will act as a permanent air-chamber and relief.

Relief for hard rugæ. In many cases the rugæ are very hard and prominent, and it is important that a small instrument be used to scrape out the impression directly over each one. The relief should be very light, and may be sufficient to insure against the chafing of the base-plate when making up the trial plate.

Many plates have been condemned as failures simply because some one of the rugæ

has been rubbed off the cast, and the denture could not go up to its place. The principle is exactly the same as that involved in placing two pieces of glass together. The two pieces of glass will stick together well; then place one grain of sand between them and they may be easily separated.

It is the careful observation of the small and apparently insignificant points that has resulted in the great achievements of modern prosthesis.—SAMUEL G. SUPPLEE, *Dental Digest*.

Collecting Material for Bacteriological Examination.—In collecting material for bacteriological examination the greatest care should be taken not to contaminate the material. The following are very good methods for collecting material:

From acute abscesses. Wash the membrane thoroughly with a mild antiseptic mouthwash (the spray may be used). Apply formalin 1 per cent., 1 minute; alcohol 70 per cent., 1 minute; acetone, 1 minute; tincture of iodine, 1 minute, on the gums, to sterilize the field of operation, and as soon as the incision is made, introduce a sterile pipet deeply into the abscess to collect the pus. The pipet is then sealed and sent to the laboratory. Instead of a pipet a stick syringe may be used.

From chronic abscesses and granulomata of teeth which are extracted. (1) Remove the tartar or other deposits from the tooth and spray the mouth and teeth with an antiseptic solution, then scrub the mucous membrane in the region of the offending tooth as carefully as possible.

(2) Pack gauze on either side of the tooth to exclude saliva, dry the mucous membrane with gauze and compressed air, and apply formalin 1 per cent., 1 minute; alcohol 70 per cent., 1 minute; acetone, 1 minute; iodine, 1 minute, to the gums.

(3) The ligamentum circulare is then cut free from the tooth, after which iodine is employed again to destroy bacteria, which always lodge just under the mucous membrane.

(4) Extract the tooth and place the forceps holding the tooth on a piece of sterile gauze, with the apex of the tooth uppermost.

(5) Curet the alveolar socket with a sterile instrument to remove the granulations, and plant some of the removed issue under anaerobic conditions, and also under aerobic conditions.

(6) Immediately after the operation clip off the apex of the removed tooth with sterile rongeur forceps, drop it into another tube of ascitic fluid broth, and grow under anaerobic conditions.

From chronic abscesses and granulomata in apicoectomy. As this operation is performed under the principles of asepsis above described, no further precautions need be taken. The amputated root is immediately picked out with sterile instruments and dropped into a tube of ascitic fluid broth, and grown under anaerobic conditions. Other cultures are made from the removed granulation tissue and grown in ascitic fluid broth under aerobic conditions.

Immediate microscopic examinations are all made by making the usual cover-glass preparations of pus obtained from acute abscesses, and from chronic conditions by smearing the end of a root or a piece of granulation tissue over the cover-glass.

The material gained from acute and chronic abscesses is inoculated on artificial media for special identification, and pure cultures may be made of the bacteria, which perhaps have already been recognized in a general way in a cover-glass preparation. The culture should be grown on various media and both under aerobic and anaerobic conditions. Anaerobic bacteria are especially hard to cultivate, and it is of greatest importance to inoculate the media without loss of time, so as not to endanger the vitality of the anaerobes.—ADAH ROBERTA HOLMES, *Journ. Calif. State Dental Association*.

Outline for Root-canal Technique.—(I) Radiograph to show number, shape, and direction of roots.

(II) Asepsis: (1) Wash or spray the mouth. (2) Paint gums and neck of tooth with tincture of iodine. (3) Isolate. (4) Wash the teeth included with alcohol. (5) Paint with tincture of iodine.

(III) Gaining access to canals: (1) Uncover entire pulp chamber. (2) Cut away buccal, lingual, and mesial walls to bring all canals into view. (3) Cut away walls to eliminate all curves possible.

(IV) Cleaning and enlarging canals: (1) XXX fine smooth broach (pathfinder) to ascertain length. (2) Large canals, barbed broaches to clean. (3) To remove old gutta-percha filling—xyloil, explorers, spiral short broach.

(V) Small canals: (1) XXX fine smooth broach file. (2) XX fine smooth broach file. (3) X fine smooth broach file. (4) XX fine Kerr file. (5) X fine Kerr file. (6) XXX (8) X fine barbed broach to curet and enlarge. (8) X fine barbed broach to curet and enlarge. (9) Fine barbed broach to curet and enlarge. (10) Fine Kerr file. (11) Apexograph or X fine barbed broach to remove

débris. (12) Sulfuric acid 30 per cent. as indicated; neutralize with sodium bicarbonate. (13) Enlarge until No. 34 plugger passes to within 2 mm. of apex.

(VI) Measurement wires and radiograph.

(VII) Dehydrating: (1) Alcohol. (2) Hot air. (3) Absorbent canal points.

(VIII) Filling canals: (1) Mark length of canal on plugger. (2) Measure size of foramen with absorbent canal point. (3) Eucalyptol to moisten canal. (4) Chloropereha, very small amount. (5) Cut cones, 1 to 3 mm. long, selected size. (6) Attach proper cut cone to No. 34 plugger and plug 2 mm. space at apex. (7) Continue until full; condense each piece thoroughly. (8) Radiograph.—E. D. COOLIDGE, *Journ. N. D. A.*

Filing and Curetting.—The process of enlarging the canal is one that requires great patience and much time. The first step is to pass the smallest size smooth broach to the apex of the root and make a mark or bend in the broach to indicate the length. This serves as a guide in the work following as to the length and direction of the canal, the broach being laid aside where it can be referred to constantly while working. Should the canal be a large one it is often possible to clean it completely with barbed broaches and prepare it for the filling, but where the canals are small and curve, as they frequently do in the mesial root of lower molars and buccal roots of upper molars, upper first bicusps, and occasionally cuspids and lower incisors, it is necessary to work with great care to avoid accidents, such as losing the canal, or plugging it up with débris, or leaving part of a broach, which is most unfortunate. Wherever the finest smooth broach will pass it is possible to enlarge and fill the canal, unless an accident occurs, which should be avoided. Where the canal is extremely small and curved, the entire operation must be carried on by the up-and-down motion, with no turning or twisting of the broach around and around. Smooth broaches may be rolled between a medium coarse file and a block of wood to make a rat-tailed file of them in the graded sizes, and with the aid of 30 per cent. sulfuric acid the extremely small and curved canal may be enlarged and straightened enough to allow the smallest Kerr file to pass, which will cut quite rapidly. It is preferable not to use the acid with anything but smooth broaches, as it weakens them, and accidents may more easily occur. The acid should be neutralized with a saturated solution of sodium bicarbonate. This process of neutralization causes effervescence, and brings much débris from the canal.

Every time the instrument is inserted in the canal, it should be passed to the apex of the root, and the canal enlarged throughout its entire length constantly to avoid losing the canal. The process of enlargement and curetment should be carried on progressively and consecutively with each size broach, one by one, until the larger sizes will pass to the apex. Should the operator become impatient and skip a size or two at a time, the result will usually be a failure, as the larger sizes will not pass to the apex, and soon a ledge is made where the canal curves, and the canal is lost, and rarely ever can be found again. The barbed broaches and files should be used alternately for curetting and raking out the filings and débris. This process should be continued until the canal plugger No. 34 or Kerr No. 1 will pass to within two millimeters of the apex.—E. D. COOLIDGE, *Journ. N. D. A.*

Root-canal Surgery With and Through Antiseptics and Disinfectants.—I believe this is safer practice than to depend upon what might be considered strict asepsis, when if all facts were known the word "strict" should not be applied. I hesitate somewhat to let this statement go out, for fear of being misunderstood. I like to see men make an honest effort to carry out asepsis in their work in every particular, especially where it is possible to introduce infectious material through an open wound or the canal of the tooth; but the point I wish to make is that asepsis as such is not necessarily essential, though very desirable, for the success of our root-canal work. As you know, I use phenol-sulfonic acid in my technique of removing pulps from teeth and cleansing the canals. Surely, while I am working with and through this agent in the canal of the tooth I am working under antiseptics at least. When the canal is cleansed, I seal in with both temporary stopping and cement a dressing of eucalyptol compound; thus again I am using an antiseptic. When at the subsequent sitting I fill the canal, I want to be certain, if I use cotton-wrapped broaches, that the cotton thereon is sterile. Here, more than at any other sitting, up to this point in this work, we need real asepsis, especially if we use, as so many do, cotton-wrapped broaches. As a matter of fact, the canal may be filled properly without using cotton on any of our broaches in most cases if eucalyptol compound was the remedy last sealed in the tooth. If this is done and we do not use cotton, we may again depend upon antiseptics and disinfectants rather than asepsis.—J. P. BUCKLEY, *Dental Items of Interest.*

HINTS, QUERIES, AND COMMENTS

A Dental Anomaly.

THE accompanying illustration is reproduced from a photograph made for me by Dr. M. H. Cryer, of a specimen showing an anomaly of formation that I have not

found anywhere described in dental literature.

The tooth was sent to me some years ago by a colleague whose letter I have lost and whose name I have unfortunately forgotten. Note is here made of that fact in the hope that the sender may recognize the illustration

and thus be able to supply the clinical history of the case.

The specimen was an upper canine of unusually large dimensions. Its abnormal size led the operator to break open the tooth in order to determine if any peculiarity of development would be brought to light by an examination of the interior formation of its pulp chamber and canal. The crown portion represented in dotted outline was broken into a number of small fragments, which were not saved, but the root portion which was sent to me revealed, as shown in the half-tone illustration, what appeared to be a diminutive canine lodged in the root-canal and adherent throughout its entire length on one side to the canal wall. The inclosed canine approximated in general form that of the tooth in which it was lodged, and its most striking feature was the normal appearance of the enamel covering of its crown portion.

It is difficult to account for the genesis of this inclosed growth except upon the hypothesis that it arose from an invagination of a portion of the dental follicle including some portion of the enamel organ, on the same principle that dermoid cysts arise from invagination and inclusion of portions of the blastoderm within the body of the organism.

Miller* has described a case of what might be termed inverted enamel formation in an anomalous canine, but his description does not indicate more than a partial invagination of the ameloblastic tissue which did not result in such a close approximation to a complete crown covering as the case here recorded.

EDWARD C. KIRK.

OBITUARY

Dr. Arwed Retter.

[SEE FRONTISPICE.]

DIED, Monday, February 25, 1918, at his home in Utica, N. Y., in his seventy-first year, ARWED RETTER, D.D.S.

Dr. Retter was born in Stuttgart, Wurttemberg, Germany, July 6, 1847. He received his early education in Stuttgart, and at the age of fifteen years he went to London, England, and thence, after a few years, came to America. Shortly after his arrival in this country he became interested in dentistry, and entered the Pennsylvania College of Dental Surgery, from which institution he was graduated in 1878. Immediately after his graduation he opened an office in Utica, N. Y., where he continued to practice until the time of his death.

Dr. Retter was quite successful in the practice of his profession, and soon built up a large practice in Utica. He was for five years president of the Utica Dental Society, and was also a prominent and active member of the Fifth District Society and of the Dental Society of the State of New York.

Dr. Retter was of a somewhat retiring nature and went little into society, but every circle in which he moved was graced and improved by his presence. He loved the company of choice friends and people of quiet tastes who were inclined to look for the better

things in life. Himself refined and educated, a deep thinker and a man of superior judgment, it was natural that his home should be the center of his thoughts, and that he should enjoy it with the members of his family and those intimate friends who were privileged to come within his circle.

He was for many years an active member of Calvary Church, and for some time served on its vestry. He was vice-president of the men's club of that church, and took a deep interest in the activities of the club.

By close application and patient study, Dr. Retter had established for himself an enviable reputation in the dental profession, and was regarded as one of the most skilful dentists in New York State. There were few dentists in the state better known or better liked. He stood for the best in his line of endeavor, and always strove to uphold the high standard of his profession. His death will be widely and sincerely mourned by hosts of friends and acquaintances throughout the state.

Dr. Retter was married in 1881 to Miss Hattie J. Hollingworth of Utica. He is survived by his widow and two daughters, two brothers, one in Germany and one in England, and three sisters.

The funeral services were held from his late home, and interment took place in the Forest Hill Cemetery of Utica.

Death of Dr. A. R. Eaton.

WE regret to announce the decease of Dr. A. R. EATON of Elizabeth, N. J. A full obituary notice of this eminent practitioner, with portrait, will be published in our July issue.—ED.

ARMY AND NAVY DENTAL NEWS

Army Medical Corps.

THE War department has not yet promulgated its decision, based on the opinion of the Judge Advocate-general of the army, in regard to the strength of the regular establishment in its relation to the numbers in grades of the commissioned *personnel* of the regular medical corps and the regular dental corps. Consequently, commissions of officers due for advancement in the latter branch have not been signed, although the officers are considered as occupying positions in the grades to which they were recently promoted on account of the increase in the dental corps. There is therefore nothing special to record in the matter beyond what has been published in these columns. In the meantime, certain promotions have been announced among officers of the Medical department. An important conference will be held during the coming week between Medical department officials and representatives of the medical colleges in order to come to some understanding in regard to the acceptance for military service of professors and instructors of those institutions. There has been a disinclination to bring into the service members of the profession who are employed in the education and training of medical students, on the theory that such educators are fully meeting the demands upon them to a greater extent than if they, individually, were commissioned as reservists. Some of this class, however, are desirous of separating themselves from the schools if such a connection is to prove a handicap, while the college authorities apprehend that such a draft on the *personnel* of the faculty can only be detrimental to the system of training young men for the profession, with its direct influence upon the list of those who would ultimately be available for military service. Some doubt is expressed as to the efficacy of any arrangement that may be made, since in the end everything depends upon the individual, and regardless of any agreement an instructor will always have the privilege of severing his relations with an institution if it is necessary in order to become eligible for appointment as a medical reservist. The branches of the Surgeon-

general's office hitherto occupying the Mills Building, a garage on M st., an apartment house on 18th st., and other places about town, were moved on Saturday and Monday into more commodious and conveniently situated quarters in the temporary structure at 7th and B sts.—*Army and Navy Register*.

Army Dental Corps.

UNDER a recent decision of the War department the dental corps of the regular army is entitled to about 300 officers, or about 90 more than it now has. Recently some 200 candidates for the appointment to this corps were examined, but the marking of the papers has not been completed. It is expected that a sufficient number will be found qualified to fill the vacancies. The National Defense Act of June 3, 1916, fixed the strength of the dental corps on the basis of 1 for every 1000 of enlisted men of the line of the army. This was amended by the act of October 6, 1917, which provides that there shall be 1 dental officer for every 1000 of the total strength of the regular army (commissioned and enlisted, line and staff) authorized from time to time by law, and that the dental corps shall consist of commissioned officers of the same grade and proportionally distributed among such grades as are now or may hereafter be provided by law for the medical corps.—*Army and Navy Register*.

Army Dental Surgeons.

FOLLOWING is a list of candidates who have qualified in the recent examination for appointment to commissions in the regular army dental corps. Recommendations will be made today [May 4th] for the commissioning of these officers as first lieutenants. There remain seventy-five vacancies in the corps after these appointments are made:

(1) John Rudolph Wikeen. (2) Richard Carlton Hoblitzell. (3) Carl Eaton Safford. (4) Charles Jefferson Denholm. (5) Harry Holmes. (6) Elmer H. Nielies. (7) Harold Jensen. (8) William Edward Blurock. (9) Daniel Sumner Lockwood. (10) Thomas Winton Deyton. (11) James Barto Mann.

(12) Avery Scott Hills. (13) George Mason Babbitt. (14) Judge William Fowler. (15) Francis Stone Adams. (16) Archie T. McGuinness. (17) Carl Howard West. (18) Edwin M. Kennedy. (19) Merle W. Catterlin. (20) Thomas Minyard Page. (21) Clarence Pefferce Jackson. (22) Chester Bumgardner Parkinson. (23) Herbert Edwin Guthrie. (24) James Harold Keith.

The English Ivory Cross Fund.

ON Saturday, February 2d, at the Bristol University, a meeting of dentists of Bristol, Eng., and district was held under the presidency of Major Aekland to hear addresses on the work of the Ivory Cross National Dental Aid Fund for Soldiers and Sailors, with the view of enlisting the sympathy and practical support of the dentists in the work. Miss Fletcher, the hon. secretary, explained that the origin of the Fund was the desire to do something in the important direction of dentistry among men in the navy and army by supplying artificial teeth as well as giving dental attention. The extensive nature of the work was indicated by the fact that over 15,000 applications had been dealt with: surgical treatment had been provided for over 11,000, and sets of artificial teeth had been provided for 2000. The work was still growing, and to meet the demands further funds were needed, as well as the practical support of the dentists of the country. Only registered dentists were allowed to do the work, and a reduced schedule of fees was arranged, for the period of the war only. Already 1200 members of the profession were assisting in the work, but more were required to cope with it. Those who were entitled to the benefits of the Fund were discharged service men, home army men, the mercantile marine, and necessitous poor, including mothers and children. As to the last-named, very little had been done, for lack of funds.—*Brit. Dental Journal*.

Navy Dental Corps.

THE Navy department has decided that the act of August 29, 1916, does not, of its own vigor, vest in an acting assistant dental surgeon, appointed under the act of August 22, 1912, the office of dental surgeon (permanent) with the right of advancement to the rank of lieutenant after five years' service (including service as an acting assistant dental surgeon). The power of appointment was left where it would have been without the specific provision made in this case, namely, in the President.—*Army and Navy Register*.

"Ulcerative Stomatitis Associated with Vincent's Organisms."

WITHIN the last few months I have had occasion to treat and thereby observe a condition of ulcerative stomatitis or gingivitis associated with spirochætæ and fusiform bacilli.

The constant finding of these organisms upon microscopical examination of the material from diseased mouths, and the absence of them in normal healthy mouths, has led me to believe that this condition has its etiology in these bacteria, and that it is not unlike the Vincent's angina of the tonsils and pharynx. In fact, in one case the infection started about the gingival tissue in the right superior and inferior molar regions, and three days later had spread to the tonsils and pharynx.

It seems to be a disease particularly prevalent and confined to our new troops training in France. As yet I am at a loss as to what to attribute it to, but to my mind it is not altogether impossible to believe that the oral neglect which is apt to follow camp life, and the close contact which actually exists between the men, may, in part at least, predispose to and promote this affection.

TREATMENT.

- The cause or causes must be removed if permanent results are to be expected. This process usually consists of placing the mouth in a hygienic condition by first removing all of the deposits present. The patient should be impressed with the importance of absolute cleanliness, and the necessity of brushing the teeth at least three times a day, especially the last thing at night, regardless of the soreness of the gums. The sloughs should be picked off everywhere, and the raw, bleeding surfaces dried and touched up with 0.05 per cent. chromic acid or 95 per cent. phenol.

As potassium chlorate is of value in these cases, a wash should be prescribed. The following is one that is useful, and which I frequently advise:

| | |
|-----------------------|---------------|
| R—Potassii chloratis, | 3jss |
| Tincturæ myrrhæ, | 3ij |
| Alcoholis, | 3jss |
| Aquæ cinnamomi, | q. s. ad f3vj |

Sig.—Use as a mouthwash three times a day, and if too strong, dilute.

Potassium chlorate (full strength) should be given in tablet form, and occasionally one should be dissolved slowly on the tongue. A cathartic should be prescribed and the bowels kept open.

Carious teeth must be filled, and after the infection is controlled, all old, broken-down

roots should be removed. All irritating factors should be eliminated, smoking and drinking reduced, and any venereal disease must be properly treated.

Strict observance of the above treatment, with co-operation between patient and dentist, will bring about prompt and satisfactory results in a surprisingly short period.—LT. WM. H. GULLIFER, D.R.C., Amer. Exp. Force, France.

—*Journ. Allied Dental Societies.*

Promotions.

Dental Reserve Corps.

[*Note.*—In our May issue we announced among the promotions in the Dental Reserve corps that of WM. C. SPEAKMAN to Captain. We have since been informed that Dr. Speakman was promoted to Major.—ED.]

THE following appointments (promotions) are announced (April 20th):

To be MAJORS: 1st Lieuts. James P. Harper and William A. Heckard.

To be CAPTAINS: 1st Lieuts. Wm. McDougall, James H. Reid, Henry D. Rand. Ormsby Keselring, Paul S. Harner, Lloyd W. Bentley, Frank A. Clear, Weston B. Estes, Edward B. Lodge, Crittenden Van Wyck, Charles A. Couplin, Joseph P. Collins, Franklin M. Huson, David A. Proctor, Fred C. Sizelan, Charles Steffens, Douglas D. Goodwin, William A. Spence, Lee F. Strickler, James A. Johnson, Carl A. Anderson, Herman E. Tipton, Chester M. Meares, Earl J. Hill, Mildred I. Merritt, Thomas F. Montgomery, Harry F. Gravelle, Earle N. Hoopman, and Joshua H. Gaskill.

Announced April 27th:

To be CAPTAINS: 1st Lieuts. Guy W. Angelo, Edward R. Danforth, Charles J. Denholm, James B. Harrington, Frank E. Hendrickson, Miguel W. Jackson, James B. Jones, George R. Lee, Ralph D. Linn, Elbert W. King, Frank B. McAdams, Earl N. McCue, and Forest DeW. Suggs.

Announced May 4th:

To be MAJOR: 1st Lient. Otis H. McDonald.

To be CAPTAINS: 1st Lieuts. Clarence J. Appleget, Albert J. T. Beatty, John E. Frates, Walton J. Graft, John W. Leggett, William B. Ley, Claude E. Markey, Wegor E. Mathison, Robert W. Meeker, Clinton T. Messner, Henley E. Miller, William L. Nance, Gilbert L. Walker, Raymond L. Anglemire, John T. Ashton, George F. Brand, Thew J. Ice, Clarence P. Jackson, Justin E. Nyce, Harry W. Porter, Floyd D. Soverel.

Announced May 11th:

To be MAJORS: Capt. Leonard G. Mitchell and 1st Lieut. Clement V. Vignes.

To be CAPTAINS: 1st Lieuts. Herman J. Brachman, James A. Campbell, Gordon B. Logan, Daniel F. McCarthy, Harold J. McGinn, Leon Reisner, Arthur C. Roblin, Wm. R. Snyder, Norman C. Spencer, Harold A. Stone, Harry M. Trafford, Harold Van Blarcom, Carl G. Anderson, Roy L. Bodine, Frank W. Boville, Merle W. Catterlin, Hubert F. Christiansen, Frank L. Cooper, Fred W. Dains, Samuel H. Davis, Pearley M. Fugler, George L. Gallagher, Grant C. Gentry, George R. Heap, Charles S. Irwin, Francis M. Kane, Chester K. Little, Otho L. McKay, Thomas G. McMartin, Seymour S. Skiff, Wm. J. Stark, Charles R. Wagner, and Raymond H. Williams.

Assignments.

Army Dental Corps.

Week ending April 20th.

Maj. Gerald D. Byrne from duty at Letterman General Hospital, San Francisco, to Fort Riley, Camp Funston, for duty.

The following to Fort Oglethorpe, medical officers' training camp, for course of instruction and return to stations: Majors Earp T. Dickmann, Wilfurth Hellman, Samuel Kaufman, Charles C. Mann, Lee B. Schrader, Walter S. Smith, and George R. Tressel. 1st Lieuts. Alvin E. Anthony, Wm. J. R. Akeroyd, Leslie D. Baskin, Clinton R. Boone, Joseph L. Boyd, Wm. B. Caldwell, Dell S. Gray, Curtis W. Hallam, Timothy Harden, Leslie S. Harlan, Winfred E. Henshaw, Claude R. Hollister, Glover Johns, Roy M. Kisner, Timothy F. Leary, Milton A. Price, Joseph L. Ralm, Samuel J. Rohde, Walter A. Rose, Wm. H. Siefert, Alexander M. Smith, Jr., Boyd L. Smith, Edward A. Thorne, Wm. T. Williams, Clarence J. Wright, and Cecil R. Hays.

Week ending May 4th.

1st Lieut. William A. Moore to Fort Crockett, Tex., for duty in coast defenses of Galveston.

Week ending May 11th.

Leave for two months on surgeon's certificate granted Lieut.-col. George I. Gunkel.

1st Lieut. Wm. A. Moore to Fort Screven for duty.

Dental Reserve Corps.

Week ending April 20th.

Capt. Wm. E. Beard to Fort Leavenworth for duty.

Capt. Claude L. Hunsicker to base hospital, Fort Des Moines, for duty.

Week ending May 11th.

Capt. Walter F. Clayton at Camp Sevier, S. C., report for duty in base hospital.

Preparedness League of American Dentists.

ORGANIZED UNDER THE AUSPICES OF THE N. D. A.

THE DENTAL COMMITTEE OF THE GENERAL MEDICAL BOARD, WHICH IS THE AGENCY FOR THE MEDICAL AND DENTAL PREPAREDNESS IN THIS WAR EMERGENCY, HAS MADE IT POSSIBLE FOR EVERY DENTIST IN THE UNITED STATES TO ASSIST IN THE WORK, UNDER THE SUPERVISION OF LIEUT. WM. A. HECKARD, D.R.C., U.S.A., STATIONED AT 50 EAST 42D ST., NEW YORK, N. Y.

REPORT FROM THE PRESIDENT.

Who should receive the services of the members of the League? Every worthy man within the draft age, whether he may or may not be in the service of his country at the time.

Let us forget all but the one thought—that we must do our utmost to help strengthen our great National Army. We must help make fighters to protect our flag, and we must do it *now*; tomorrow may be too late.

One of our members recently arose at 3 A.M. and worked until 5 that one of "our boys" might go away in comfort. It is noble work, and thousands of instances similar to this one might be related. The pride we feel in the way our profession is meeting the crisis cannot be expressed in mere words.

Every man you make dentally fit will fight for you in France. Have an army of your own.

ALL LEAGUE SERVICE MUST BE FREE.

It is well, perhaps, at this time to remind our members that all dental service rendered in the name of the League must be free. There can be no deviation from this rule without nullifying the great principle upon which our organization is founded. We are rendering an inestimable service to our country, and when we shall have completed our work, let it be said that we gave freely, gladly, and with true patriotic spirit.

THIRD ANNUAL MEETING OF THE LEAGUE.

Our third annual meeting will be held on August 7th, in conjunction with the National Dental Association, Chicago, Ill. We are arranging a program which will be of absorbing interest, and urge every member who belongs to the N. D. A. to join us in the enjoyment of the good things we are preparing.

J. W. BEACH, *President*.

REPORT FROM THE DIRECTOR-GENERAL.

Regarding the editorial from a western newspaper in which the "Questionnaire" asking dentists to join the League was criticized, inclosed with the letters you sent me to read. I would say that it looks very much like German propaganda, although I presume it was printed in all innocence, but if the editor had stopped awhile to consider it, undoubtedly he would have adopted another form of criticism.

The Preparedness League is working under the supervision of the Surgeon-general's office. That being the case, one must realize that before this questionnaire was made up, very serious consideration was given the form of the questions, and each question was devised for a specific purpose. The general purpose of all questions is to help us in securing new members for the Preparedness League, in order that the work may be increased to such an extent that the League may be of more efficient help to the Government.

THE QUESTION OF CHARGING FOR SERVICE.

Regarding the matter of paying for dental service by those who are well able to pay: A dentist is asked to give but one hour a day to the registrants: he would therefore be giving but one hour of free dental service whether the man could pay or not, and this surely is not a great hardship on anyone. If the registrant pays for the service, then it immediately ceases to be voluntary service on the part of the dentist, and is therefore not Preparedness League work. There is no objection to a man who is able to pay for the work going to his own dentist to have the work done and paying for it, but such service should not be recorded as free dental service or as Preparedness League work, as it is

work done strictly in a private capacity, and is in no way connected with volunteer service. On the other hand, if any registrant, however well able to pay, is willing to accept free service at the hands of the Preparedness League, it seems very little for the League to take care of him in comparison with the man's offering his life for our protection, and I should dislike very much to hear that any dentist would refuse volunteer service under these circumstances.

CONTINUOUS APPOINTMENTS NOT PRACTICABLE.

Making appointments with individual members of the drafted men is, I think, not practicable, for the reason that it is only through organized channels that the dentists offering their services can be assigned their fair proportion of the work. If work were continued on each mouth until it was put in good condition, it would work out to the advantage of the few and the disadvantage of the many. If a registrant needs a second or third appointment to make his mouth dentally fit, refer him back to the League's headquarters for such appointments, and if time permits there is no doubt that he will be taken care of; meanwhile, those who come after him are not being neglected.

On the other hand, if a registrant requires a second or third appointment and the dental operator is interested enough in his case to finish the work, then additional appointments may be made with the registrant, providing they do not interfere with the time he has already pledged the League. In other words, only one hour is to be given each registrant unless other provision has been made for

him either by the dental operator or by the Preparedness League. The *once over* for each registrant is the important thing to be borne in mind.

BROKEN APPOINTMENTS.

When appointments, either first or second, are not kept, the result of course is loss of time. When this happens it is unfortunate and must be considered a part of our personal sacrifice, as there seems to be no way to guard against it. New appointments should not be given those who break their first appointments, but they should be referred back to the League's Headquarters and sent back to the state director.

CHAS. F. ASH, *Director-general.*

FORM 3-C CARDS.

EACH dentist should chart the operations performed, sign his name, and apply the stickers furnished by each state director or county director. If the operator has no sticker, cross out the name of the selective on the address side and write Lieut. W. A. Heckard, D.R.C., 50 East 42d st., New York City, across the card, and mail at once.

FORM 18 CARD.

When the work on each registrant is finished it should be recorded on form 18 card, and when this form 18 card is filled up and duly signed it should be dropped in the box and sent back to the state director. Each card takes care of itself, and records work done to date.

R. OTTOLENGUI,
Director of Publicity.

SPECIAL NOTICE.

Forsyth Dental Infirmary for Children.

PERMANENT STAFF APPOINTMENTS.

A competitive examination of graduates in dentistry (of less than three years' standing) for appointments to positions on the permanent staff for full and one-half time service will be held early in June at the Infirmary.

Appointments will be made for one or two years as follows: Full-time service, requiring operating five and one-half days a week at a salary of \$1000 a year. Half-time service, requiring operating six half-days a

week, either forenoon or afternoon, at a salary of \$400 a year.

These appointments will be made subject to satisfying the requirements of the Massachusetts State Board of Registration in Dentistry, and to qualifying in the practical work of the clinics during one month's trial.

Members of this staff will be entitled to the advantages of reports and clinics by experts in the various branches of dentistry from different parts of the world, in addition to the numerous regular clinics and lectures. Operators after serving four months are eligible, by qualifying, for appointments in the special

clinics where postgraduate work is given. The operators on this staff have the advantage of the clinics and lectures of the Postgraduate School of Orthodontia.

The Infirmary clinics provide unusual advantages in the various departments of the institution where operative dentistry, orthodontia, nose and throat and oral surgery, extracting, novocain technique, radiography, pathological diagnosis, and research work are continually carried on. The average number of cases treated daily is more than 450 in all departments. All material and necessary operating instruments will be furnished. Up-to-date apparatus, including electric engines,

sterile instrument trays, fountain cuspidors, compressed air, and the modern operating-room type of laboratories, are available for use.

A diploma for service will be issued by the trustees to each member of this staff who has completed his term of service in a satisfactory manner.

Applications for the above positions should be made at once.

Information and the date of the examination will be furnished to those interested.

HAROLD DEW. CROSS, *Director*,
140 The Fenway, Boston, Mass.

American Medical Association.**Section on Stomatology.**

Following is the program for the American Medical Association, Section on Stomatology, for the meeting to be held in Chicago, June 11 to 14, 1918:

Chairman's Address. Dr. Frederick B. Noyes, Chicago.

(1) "Chancre of the Lip Following Injury with Dentist's Emery Disk." Dr. Adelbert M. Moody, Chicago.

(2) "An Analysis of Two Hundred Cases of Malignant Diseases in the Oral Cavity by Electro-thermic Methods, or in Combination with Operative Surgery, X-rays, or Radium." Dr. Wm. L. Clark, Philadelphia, Pa.

(3) "Treatment of Epithelioma of the Jaws and Cheek with Heat and Radium." Dr. Gordon B. New, Rochester, Minn.

Discussion—Dr. Albert T. Ochsner, Chicago, Ill.

(4) "The Lipoids of Tumors of the Dental System." Dr. Kaethe W. Dewey, Chicago, Ill.

(5) "The Genesis of the Epithelial Débris in the Peridental Membrane, Nasmyth's Membrane, and the Granular Layer of Tomes." Dr. Eugene S. Talbot, Chicago, Ill.

(6) "Additional Roentgenographic Studies of Infections of the Maxillary Bones." Dr. Arthur D. Black, Chicago, Ill.

(7) "Microscopic Studies of Diseased Peridental Tissues, Illustrated by Stereopticon." Dr. Edward H. Hatton, Chicago, Ill.

(8) "Absorption of the Roots of Teeth." Dr. Herbert A. Potts, Chicago, Ill.

(9) "Neuralgia Dentalis." Dr. Kurt H. Thoma, Boston, Mass.

(10) "Longitudinal and Transverse Sectional Views of the Accessory Sinuses of the Human Cranium, Cut Parallel, and at Right Angles to the Nasal Septum." Dr. Geo. Edward Fell, Chicago, Ill.

(11) "Fractures of the Bones of the Face, with Complication." Dr. Vida Latham, Chicago, Ill.

(12) "Fractures and Dislocations of the Jaws." Dr. Chalmers J. Lyons, Ann Arbor, Mich.

(13) "A New Surgical Procedure for Operating in Cases of Suppurative Gingivitis with Alveolar Involvement." Dr. Arthur Zentler, New York City, N. Y.

The officers of the Section cordially invite those who are interested in the program to be present, and to take part in the discussions.

FREDERICK B. NOYES, *Chairman*,
EUGENE S. TALBOT, *Sec'y*.

National Dental Association.

TWENTY-SECOND ANNUAL MEETING.

Chicago, August 5th to 9th.

SPECIAL ANNOUNCEMENT OF HOTELS AND GARAGES.

THE National Dental Association will hold its Twenty-second Annual Meeting in Chicago, August 5-9, 1918. The headquarters will be at the Auditorium and Congress Hotels, situated on Michigan ave., cor. Congress st. All meetings, clinics, and exhibits will be held in these two hotels, which are connected by an underground tunnel.

The important announcement at this time must be the warning: RESERVE YOUR ROOMS AT ONCE. Make reservations by mail direct to the hotel of your choice. Arrangements for parking cars should be made direct to the garage.

Hotels.

Following are the rates of the two hotels:

Auditorium Hotel (Michigan Boulevard and Congress st.): Single room without bath, \$1.50 and \$2.00 per day. Single room with bath, \$2.50 to \$4.00 per day. Double room without bath, \$2.50 and \$3.00 per day. Double room with bath, \$4.00, \$5.00, and \$6.00 per day.

Congress Hotel and Annex (Michigan ave. and Congress st.): Room, detached bath (one person), \$2.00, \$2.50, \$3.00 per day. Room, private bath (one person), \$3.00, \$3.50, \$4.00, \$5.00, \$6.00 per day. Room, detached bath (two persons), \$3.00, \$4.00, \$5.00 per day. Room, private bath (two persons), \$5.00, \$6.00, \$7.00 per day. Suites: Two connecting rooms, private bath (two persons), \$6.00 to \$10.00 per day. Three or four persons, \$8.00 to \$14.00 per day.

Corner suites: Parlor bedroom and private bath, \$10.00 to \$50.00 per day.

Garages.

The following is a list of garages and rates:

CITY AUTO PARKING COMPANY.

(A. V. Jackson, Gen. Mgr.,

Michigan ave. and Lake st., Chicago, Ill.)

Our rates for storage are \$1.00 for the first 24 hours, and 75 cents each additional 24 hours. At these rates cars can be taken out for driving and reparked during the same 24-hour period at same charge.

DOWN TOWN GARAGE.

(A. J. Bemmer, Mgr.,

Michigan blvd. and Eighth st.)

"We are prepared to take care of thirty or forty cars during your convention, at a

special rate of 75 cents per day, providing they notify us of their identity as members of your association."

One thousand cars can be parked in Grant Park (on the Lake Front) free. The city of Chicago furnishes policemen to watch these cars.

J. P. BUCKLEY,

Chairman Publicity Committee.

GENERAL CLINIC.

Arrangements are sufficiently advanced to promise the members of the Association that the General Clinic will be one of the great features of the 1918 meeting.

In conference with officers of the National Dental Association, the committee in charge of the General Clinic carefully considered the nature of the clinic to be presented this year. After trying for the past few years new features in conducting the clinic program, it is the belief that a greater number will be served and benefited by holding a General Clinic, grouped in sections: Operative, Prosthetic, Crown and Bridge Work, Orthodontia, and Prophylaxis.

To make it National in character, the presidents of the different state societies were requested each to appoint two clinicians and two associates from his state society.

Up to date, thirty-nine state societies are represented, and the remaining nine will be represented before the publishing of the official program.

Far-away Alaska is sending two, and two associates, and to make the Clinic more than National—in fact, an "Allied" affair—the Canadian Dental Association has promised ten of the best clinicians in the Dominion. In addition, there will be a few unit clinicians who will demonstrate principles that require more than two men.

It is safe to say that this Clinic will be unique in the sense that every man on the program will either be present or be represented by his associate.

DON M. GALLIE.

Chairman General Clinic.

[AT CHICAGO.]

National Association of Dental Examiners.

THE next meeting of the National Association of Dental Examiners will be held in Chicago, Ill., August 5 and 6, 1918, at the Auditorium Hotel.

For further information address

J. A. WEST, Sec'y.

417 Utica Bldg., Des Moines, Iowa.

[AT CHICAGO.]

National Association of Dental Faculties.

THE next annual meeting of the National Association of Dental Faculties will be held in the Green Room of the Congress Hotel, Chicago, Ill., August 2, 1918, at noon. The Executive Committee will meet at 10 A.M. on the 2d. The meeting will continue through August 3d.

CHAS. C. ALLEN, *Sec'y.*

N. W. cor. 10th and Troost, Kansas City, Mo.

[AT CHICAGO.]

American Society of Orthodontists.

THE eighteenth annual meeting of the American Society of Orthodontists will be held August 1, 2, and 3, 1918, at the Edgewater Beach Hotel, Chicago, Ill.

This will be an excellent meeting. It is advisable to make your reservations early.

F. M. CASTO, *Sec'y.*

Rose Bldg., Cleveland, Ohio.

[AT CHICAGO.]

Psi Omega Fraternity.

THE National Alumni Chapter of the Psi Omega Fraternity has established headquarters during the National Dental Association meeting at Room 230, Auditorium Hotel.

The business session of the National Alumni Chapter will be held in the New Ballroom of the Auditorium Hotel, Monday, August 5th, at 2.00 P.M.

The Psi Omega banquet will be held in the Florentine Room of the Congress Hotel at 7.00 P.M., Monday, August 5th.

Psi Omegas who expect to attend the banquet should communicate at once with Dr. M. M. PRITZ, 4235 Lake Park ave., Chicago.

[AT CHICAGO.]

Delta Sigma Delta Fraternity.

THE thirty-fourth annual meeting of the Supreme Chapter of Delta Sigma Delta Fraternity will be held in the Florentine Room of the Congress Hotel, Chicago, on Monday, August 5, 1918, at 9 A.M.

Headquarters of the Fraternity will be at the same hotel, where the annual banquet will also be held in the evening, in the Gold Room. (Notify Dinner Committee at once.)

By order of the Supreme Chapter.

HY. W. MORGAN, *Supreme Gr. Master.*R. HAMILL D. SWING, *Supreme Scribe.*

Northern Ohio Dental Association.

THE annual meeting of the Northern Ohio Dental Association will be held June 6, 7, and 8, 1918, at Toledo, Ohio.

C. H. CLARK, *Sec'y.*

Youngstown, Ohio.

Georgia State Dental Society.

THE semi-centennial meeting of the Georgia State Dental Society will be held in Atlanta, Ga., June 12, 13, and 14, 1918, when this society will celebrate its fiftieth anniversary.

North Carolina Dental Society.

THE North Carolina Dental Society will meet on June 19 to 21, 1918. Headquarters, Oceanic Hotel, Wilmington, N. C.

W. T. MARTIN, *Sec'y.*

Maine Dental Society.

THE fifty-third anniversary meeting of the Maine Dental Society will be held in the City-hall, Portland, Me., June 26 to 28, 1918.

I. E. PENDLETON, *Sec'y.*
Lewiston, Me.

Washington State Dental Society.

THE Washington State Dental Society will hold its next meeting in Spokane, Wash., June 27, 28, and 29, 1918.

A. STARKE OLIVER, *President*,
FRANK B. LYNOTT, *Sec'y*,
249 Peyton Bldg., Spokane, Wash.

Tennessee State Dental Association.

THE fifty-first annual meeting of the Tennessee State Dental Association will be held in Nashville, Tenn., June 17, 18, and 19, 1918.

GEO. L. POWERS, *Sec'y.*
Paris, Tenn.

South Carolina State Dental Association.

THE annual meeting of the South Carolina State Dental Association will be held at the Jefferson Hotel, Columbia, S. C., June 27, 28, and 29, 1918.

W. BUSEY SIMMONS, *President*.
ERNEST C. DYE, *Sec'y*.

Kentucky State Dental Association.

THE next annual meeting of the Kentucky State Dental Association will be held at Lexington, Ky., June 13, 14, and 15, 1918. An "amalgam program" of special interest.

Address all correspondence to

W. M. RANDALL, *Sec'y*,
1035 Second st., Louisville, Ky.

Northwestern University Dental School.

THE Northwestern University Dental School Alumni Association will hold the annual Home-coming Clinic, 31 W. Lake st., Chicago, Ill., on June 10 and 11, 1918. Special features have been provided which will insure a successful and interesting meeting. Make your arrangements now.

M. M. PRINTZ, *Sec'y*.
4235 Lake Park ave., Chicago.

Postgraduate Dental Meeting:

Alabama—Mississippi—Texas—
Louisiana.

(1) *Place of meeting.* New Orleans, at the Grunewald Hotel.

(2) *Date.* To avoid interfering with dental college exercises and dental examining board meetings, and to be assured of pleasant weather, the date June 3, 4, 5, and 6 has been selected.

(3) In order to give each member an equal opportunity to get all that is possible and not congest the meeting the membership will be limited to 350 members.

(4) Membership cards will be issued only to members in good standing in their state dental societies, and to dentists in the army and navy dental corps.

(5) The registration books will be closed May 27th (one week before the meeting) to all except members of the army and navy dental corps.

(6) *Fee.* Owing to increased cost of postage and stationery and all other expenses, the membership fee to the general meeting will be ten dollars. Special courses following the general meeting, fifteen dollars for each course.

(7) No one will be issued a special course card unless he has registered for the general meeting.

The subjects to be taught at the next meeting will be as follows:

"Nerve Blocking." Dr. Arthur E. Smith, Chicago.

"Technique of Root-canal Preparation, Treatment and Filling." Dr. Elmer S. Best, Minneapolis.

"Full Upper and Lower Dentures." Dr. Rupert E. Hall, Chicago.

"Exodontia." (Instructor to be selected.)

General Chairman—J. J. Sarrazin, 424 Godechaux Bldg., New Orleans, chairman Committee on Interstate Relations.

General Secretary—Leo C. Dempsey, 943 Jackson ave., New Orleans.

Ask yourself the question, Can I afford to miss this meeting? Send your application for membership to the Four States Postgraduate meeting, with your check for ten dollars, to your state chairman for indorsement and transmission by him to Dr. L. C. Dempsey, the general secretary. Members of the Louisiana State Dental Society can apply direct to Dr. Dempsey with membership fee inclosed.

J. P. WAHL, *Ch'man Publicity Com.*,
1135 Maison Blanche, New Orleans, La.

Florida State Dental Society.

THE Florida State Dental Society will hold its next annual meeting at the Atlantic Beach Hotel, Atlantic Beach, Fla., on June 20, 21, and 22, 1918, where fishing, golfing, and surf bathing is unsurpassed.

A fine program is being planned. All ethical practitioners of this and other states invited.

For further particulars address

D. D. CREWS, *Sec'y*,
Fort Myers, Fla.

California State Dental Association.

THE California State Dental Association will hold its regular annual session for the year 1918 in San Francisco, July 8 to 13, 1918.

We will conduct our meeting this year on the Oklahoma plan, and feel that we can assure all who attend a pleasant as well as a profitable meeting. Further information may be obtained by addressing

JOHN E. GURLEY, *Sec'y*,
350 Post st., San Francisco.

New Jersey State Dental Society.

THE forty-eighth annual convention of the New Jersey State Dental Society will be held on July 17, 18, and 19, 1918, on Young's Million Dollar Pier, Atlantic City, N. J.

The entire convention will be held on the pier. Machinery Hall will be used for the exhibits. Those who attended last year will remember the magnificent display of dental goods, and Dr. S. I. Callahan of Woodstown, N. J., chairman of the Exhibit Committee, with 25,000 square feet of space, has promised an exhibit greater than that of 1917.

The Essay Committee, under the direction of Dr. C. M. F. Egel of Westfield, will present two or three essayists of prominence—names and subjects to be announced.

All meetings for the presentation of papers as well as the business meetings will be held in the Greek Temple, out on the pier.

The headquarters of the society will be at the pier entrance. Mail may be directed to exhibitors, clinicians, or members in care of the Secretary New Jersey State Dental Society, Young's Million Dollar Pier.

A cordial invitation is extended to ethical practitioners.

JOHN C. FORSYTH, *Sec'y*,
430 E. State st., Trenton, N. J.

American Institute of Dental Teachers.

AT the last annual meeting of the American Institute of Dental Teachers, held at Pittsburgh, Pa., January 29 to 31, 1918, the following officers were elected: Dr. A. W. Thornton, McGill University, Department of Dentistry, Montreal, Que., president; Dr. R. W. Bunting, Ann Arbor, Mich., vice-president; Dr. Abram Hoffman, 381 Linwood ave., Buffalo, N. Y., secretary-treasurer. Executive Board—A. D. Black, Chicago, Ill., G. S. Millberry, San Francisco, Cal., and A. H. Hipple, Omaha, Nebr.

The next annual meeting will be held January 28, 29, and 30, 1919, the place of meeting to be announced later.

Indiana Board of Examiners.

THE next meeting of the Indiana State Board of Dental Examiners will be held at the State-house, Indianapolis, June 17th to 22d inclusive. Applications and other information may be obtained by addressing

H. C. MCKITTRICK, *Sec'y*,
Indianapolis, Ind.

South Carolina Board of Examiners.

THE annual meeting of the South Carolina Board of Dental Examiners will be held at The Jefferson, Columbia, S. C., beginning promptly at 9 o'clock, Monday morning, June 24, 1918.

All applications must be in the hands of the secretary by June 14th. Application blanks and full information may be obtained by addressing

R. L. SPENCER, *Sec'y*,
Bennettsville, S. C.

Mississippi Board of Examiners.

THE Mississippi Board of Dental Examiners will hold its next annual meeting at the State Capitol building in Jackson, on the third Tuesday in June 1918, at 8 A.M. Fee for examination \$10. Diploma from recognized school and certificate of moral character required. No reciprocity or interchange. For further information address

B. J. MARSHALL, *Sec'y*,
Marks, Miss.

Connecticut Dental Commission.

THE Dental Commissioners of Connecticut will meet at Hartford, June 20, 21, and 22, 1918, to examine applicants for license to practice dentistry, to examine applicants for dental hygienist's license, and to transact any other business proper to come before them. For blanks and further information, address

EDWARD EBERLE, *Recorder*,
902 Main st., Hartford, Conn.

Washington Board of Examiners.

THE Washington State Board of Dental Examiners will hold their next meeting at Seattle, Wash., May 30 to June 5, 1918. Address all communications to

FRANK B. LYNOTT, *Sec'y*,
249 Peyton Bldg., Spokane, Wash.

Michigan Board of Examiners.

THE next meeting of the Michigan State Board of Dental Examiners will be held at the Dental College, University of Michigan, Ann Arbor, Michigan, June 17th to 22d inclusive. Applications and other information may be obtained by addressing

B. S. SUTHERLAND, *Sec'y*,
Owosso, Mich.

North Carolina Board of Examiners.

THE next meeting of the North Carolina State Board of Dental Examiners will be held at Wrightsville Beach, Wilmington, N. C., beginning promptly at 9 o'clock on Monday morning, June 17, 1918. For further information and application blanks address

F. L. HUNT, *Sec'y*,
Asheville, N. C.

Rhode Island Board of Registration.

A MEETING of the Rhode Island Board of Registration in Dentistry for the examination of candidates will be held in the State-house, Providence, R. I., June 18, 19, and 20, 1918. Applications, accompanied with the proper fee, should be in the hands of the secretary by June 11th.

For further information address

ERNEST A. CHARBONNEL, *Sec'y*,
139 Mathewson st., Providence, R. I.

Massachusetts Board of Examiners.

A MEETING of the Massachusetts Board of Dental Examiners will be held in Boston, Mass., June 22 to June 29, inclusive, 1918, for the examination of candidates for registration. All applications must be in the hands of the secretary on or before June 13th. For further information address

GEORGE H. PAYNE, *Sec'y*,
29 Commonwealth ave., Boston, Mass.

Missouri Dental Board.

THE Missouri Dental Board will hold its next regular meeting for examining applicants who desire to register in Missouri, at Jefferson City, Monday, Tuesday, and Wednesday, June 10, 11, 12, 1918.

Applications and fees must be in the hands of the secretary prior to beginning the examination. The practical examination (given at the colleges in Kansas City on Monday and Tuesday, May 13th and 14th) will be given at the St. Louis colleges on Friday and Saturday, June 7th and 8th. It will be more convenient for those taking the examination to take the practical work at colleges if they can so arrange it.

V. R. McCUE, *Sec'y*,
Cameron, Mo.

Pennsylvania Board of Examiners.

THE next examination of the Pennsylvania Board of Dental Examiners will be held in Philadelphia and Pittsburgh on Wednesday, Thursday, Friday, and Saturday, June 12, 13, 14, and 15, 1918.

The examination in practical work will be in the Evans Dental Institute, 40th and Spruce sts., Philadelphia, and at the University of Pittsburgh, Pittsburgh, on Wednesday, June 12th. The examination in operative work will be held at 8.30 A.M. in each city and the prosthetic work at 1.30 P.M. Applicants are required to furnish all instruments and a patient for the operative work.

The theoretical examination will be held in Musical Fund Hall, Philadelphia, and College of Pharmacy, Pride and Bluff sts., Pittsburgh, beginning at 9 A.M. on Thursday, June 13th.

Application papers can be secured from the department of Public Instruction, Harrisburg.

ALEXANDER H. REYNOLDS, *Sec'y*,
4630 Chester ave., Philadelphia.

Wisconsin Board of Examiners.

THE Wisconsin State Board of Dental Examiners will hold their spring examination, June 17 1918, at the Marquette College, Ninth and Wells sts., Milwaukee, Wis. All applications must be in the secretary's hands thirty days before examination.

F. A. TATE, *Sec'y*,
Rice Lake, Wis.

Oklahoma Board of Examiners.

THE Oklahoma Board of Dental Examiners will meet in regular semi-annual session at Oklahoma City, Okla., beginning Monday, June 10, 1918. For further information write

H. OVERBEY, *Sec'y*,
Ryan, Okla.

Tennessee Board of Examiners.

THE Tennessee State Board of Dental Examiners will hold their next meeting June 11th to 15th, inclusive, at the Hermitage Hotel, Nashville, Tenn.

W. G. HUTCHISON, *Sec'y*,
Nashville, Tenn.

Texas Board of Examiners.

THE next regular examination of the Texas State Board of Dental Examiners will be held in San Antonio, Texas, beginning June 17, 1918, at 9 A.M. No diplomas exchanged; no reciprocity.

The application fee of \$25 should be in the hands of the secretary not later than June 12th. For further particulars and application blanks address

HARRISON B. CAVE, *Sec'y*,
810-14 Wilson Bldg., Dallas, Texas.

Alabama Board of Examiners.

THE Board of Dental Examiners of Alabama will conduct an examination of applicants for license to practice dentistry in Alabama at the Birmingham Dental College, in Birmingham, beginning at ten o'clock Monday morning, June 17, 1918. All applications, accompanied by necessary fee, with proper credentials, should be in the hands of the secretary-treasurer at least one week before the examinations begin.

For further information, application blanks, etc., address

H. CLAY HASSELL, *Sec'y-Treasurer*,
Tuscaloosa, Ala.

Nebraska Board of Examiners.

THE next regular meeting of the Nebraska State Board of Dental Examiners will be held June 17, 18, 19, 20, and 21, 1918, at Lincoln, Nebr.

S. A. ALLEN, *Sec'y*.

Idaho Board of Examiners.

THE Idaho State Board of Dental Examiners will hold their next session at Boise, Idaho, June 10, 11, 12, and 13, 1918.

A. M. JACOBSEN, *Sec'y*,
Pocatello, Idaho.

Iowa Board of Examiners.

THE next meeting of the Iowa State Board of Examiners will be held at Iowa City, Iowa, commencing June 3, 1918, at 9 A.M.

For further information address

J. A. WEST, *Sec'y*,
417 Utica Bldg., Des Moines, Iowa.

New Jersey Board of Registration.

THE State Board of Registration and Examination in Dentistry of New Jersey will hold their annual meeting and examination in the Assembly chamber, at the State-house, Trenton, N. J., on June 24, 25, 26, 27, and 28, 1918. License fee \$25, re-examination \$10.

Applications must be filed complete ten days before the date of the examinations. Address all communications for further particulars to

JOHN C. FORSYTH, *Sec'y*,
430 E. State st., Trenton, N. J.

Vermont Board of Examiners.

THE next meeting of the Vermont Board of Dental Examiners for the examination of candidates to practice in Vermont will be held at the State-house, Montpelier, commencing at 2 P.M., on June 24, 1918, and continuing for three days.

To be eligible for examinations a candidate must be (1) twenty-one years of age, (2) a graduate of a high school of the first class, and (3) of a reputable dental college.

Applications must be in the hands of the secretary not later than June 15th. For further information apply to

HARRY F. HAMILTON, *Sec'y*,
Newport, Vt.

Montana Board of Examiners.

THE Montana State Board of Dental Examiners will hold a session for examination July 8, 9, 10, and 11, 1918, at Helena, Mont. Applications should be in the hands of the secretary fifteen days before the meeting.

G. A. CHEVIGNY, *Sec'y.*

107 Yegen Bank Bldg., Butte, Mont.

South Dakota Board of Examiners.

THE next meeting of the South Dakota State Board of Dental Examiners will be held at Sioux Falls, S. D., beginning promptly at 9 o'clock, Monday morning, July 1, 1918.

All applications must be in the hands of the secretary by June 24th. Fee for examination \$25. No reciprocity or interchange. Full information and application blanks may be received by addressing

L. S. SPENCER, *Sec'y.*
Watertown, S. D.

North Dakota Board of Examiners.

THE next meeting of the North Dakota State Board of Dental Examiners will be held at Fargo, July 9, 1918. All applications and credentials must be in the hands of the secretary July 1st. For application blanks or further information address

W. E. HOCKING, *Sec'y.*
Devils Lake, N. D.

Maine Board of Examiners.

THE Maine Board of Dental Examiners will hold their regular examination, beginning July 1, 1918, at 8.30 A.M. at the State-house.

All applications and fee, \$20, must be in the hands of the secretary by June 21, 1918.

The examination for DENTAL HYGIENISTS will be given at the same time; fee \$10.

WILL S. PAYSON, *Sec'y.*
Castine, Maine.

UNITED STATES PATENTS

PERTAINING OR APPLICABLE TO DENTISTRY

ISSUED DURING APRIL 1918.

April 2.

- No. 1,261,339, to EDWARD H. ANGLE. Orthodontic appliance.
- No. 1,261,585, to WM. L. MAYO. Combination toothbrush and powder-box.
- No. 1,261,737, to HUGH D. MORGAN. Means for attaching an artificial tooth to a backing or bridge plate.
- No. 121,030, to JENNIE AGAN. Trade-mark for face creams, face powder, tooth-powder, tooth-paste, tooth-washes, hair tonic, foot-powder, and all cosmetics.
- No. 121,040, to ALBERT E. BROWN. Trade-mark for antiseptic mouth-wash.

April 9.

- No. 1,262,184, to JOHN MICHAEL DONAHOE. Means for retaining lower partial dentures in the mouth.
- No. 1,262,464, to CHAS. DIERKE. Dental floss holder.
- No. 1,262,465, to FREDERICK C. DOHRMANN. Antiseptic toothbrush holder.
- No. 1,262,520, to JOHN A. KELLER. Toothbrush holder.

April 16.

- No. 1,262,629, to GEORGES A. BROUILLET. Process of filling teeth.

- No. 1,262,705, to WM. F. SHAW. Anchor attachment for removable bridge work.
- No. 1,263,234, to OSCAR J. HANSON. Dentist's lamp.
- No. 1,263,311, to WM. J. CURRY. Artificial tooth-fastening.
- No. 1,263,313, to JAS. S. DONNELLAN. Attaching means for artificial sets of teeth.
- No. 121,219, to SOCIETY OF CHEMICAL INDUSTRY IN BASLE. Trade-mark for certain pharmaceutical preparations to be used as antiphoetics, anesthetics, analgesics.
- No. 121,231, to WILLIAMS BRUSH Co. Trade-mark for toothbrushes, nail-brushes, and hair-brushes.

April 23.

- No. 1,263,752, to ISADORE A. EPPSTEIN. Tooth structure.

April 30.

- No. 1,264,496, to LEO E. EYSLIN. Porcelain crown.
- No. 1,264,615, to HIRAM O. COWDRICK. Artificial tooth.
- No. 121,386, to HENRY WILLARD ALLEN. Trade-mark for tooth-paste, liquid tooth-wash and dental soap.

ORIGINAL COMMUNICATIONS

Cysts of the Dental System.

By KAETHE W. DEWEY, M.D., Chicago, Ill.

From the Research Laboratory of the College of Dentistry, Univ. Illinois.

HISTORICAL.

CYSTS of the dental system are generally classified as root-cysts, follicular cysts, and multilocular cysts, and by the majority of authorities are believed to arise from anomalies and from remnants of the enamel organ. Root-cysts and follicular cysts are more frequently found in the upper jaw, while multilocular cysts and their solid forerunners are with rare exceptions found in the lower jaw.

As to their origin, root-cysts are believed to occur in connection with chronic inflammations of the periodontal membrane. They are by far the most frequent. Of 416 cases of cysts which Rosenstein* observed, 394 were root-cysts, 13 follicular cysts, and 9 could not be determined. Astachoff† examined

98 pieces from jaws carrying gangrenous teeth, and in these found 36 root granulomas and 52 root-cysts. Not rarely the root projects into the cystic cavity; in larger cysts several roots may be found.

Follicular cysts are independent of caries of the teeth, and as a rule occur during the second dentition. They are believed to originate from dilatation of a tooth follicle or misplacement and malformation of a tooth germ. Very frequently they contain one tooth, less frequently several teeth, the crowns of which are directed toward the lumen. Sometimes the tooth is lacking in the alveolar process where the toothlike cyst is located.

Multilocular cysts belong to the class of solid epithelial tumors in the central portion of the jaw. This is simply the stage preceding the cyst formation.

Root-cysts and follicular cysts are very much alike as to their form and growth. The most characteristic feature of all is the frequent presence of squamous epithelial cells which occur as plugs or ten-

† "Ueber die Pathogenese der Zahnwurzelzysten." *D. Monatsschr. f. Zahnheilk.*, 1909, xxvii, 644.

drills extending through the granulation tissue, or as a lining of the cystic cavity. They also occur in root granulomas, which so frequently develop into root-cysts. Römer,* who examined 100 specimens of root granulomas, divides them into two distinct classes according to the presence or absence of epithelial cells. The latter type is called by him "simple granuloma," and Römer maintains that such granulomas never develop, in fact never can develop, into cysts for the very reason that they do not contain any epithelial cells.

According to most writers these epithelial cells are derived from the so-called *débris épithéliaux paradentaires* of Malassez, i.e. the cell clusters and cords which occur almost constantly in the peridental membrane in man and the higher animals. There is not yet absolute agreement among authors as to the origin, nature, and function of these cells. The majority of recent writers consider them as the remains of that portion of the enamel organ which, as Hertwig† and Von Brunn‡ have shown, normally extends downward as an epithelial sheath around the root. After the eruption of the tooth this sheath is gradually broken up by the fibers of connective tissue which extend from the alveolar periosteum to the dentin of the developing root; but remnants persist throughout life.

BLACK'S GLANDULAR EPITHELIAL CELLS.

The histologic structure, distribution, and arrangement of these cells have been thoroughly studied and well described, among other recent writers, by Noyes§

* Römer. "Periodontitis chronica hyperplastica circumscripta." *Scheff's Handb. d. Zahnheilk.* 1909, ii. 1 Abt. 673.

† Hertwig, "Entwickelungslehre." Jena, 1906.

§ Noyes, "A Textbook of Dental Histology and Embryology." Philadelphia and New York, 1915.

and Black.* These two authors are inclined to doubt the mere embryonic character of these cells. Noyes, although he accepts their embryonic origin, considers it as apparently improper and illogical to suppose that embryonic débris would persist through life, if it were useless to the organism. He is guarded in his statements concerning the possible function of these cell clusters, because of the failure of extensive attempts to discover a connection with the epithelial cells lining the gingival space, or a duct or a lumen, in these strings.

Black expresses more positive views. According to him, the epithelium of the enamel organ, as it breaks up and floats away, is absorbed and disappears completely. "These cells," he writes, "seem to have nothing whatever in common with the epithelial cells scattered in strings in the peridental membrane. They are not like them. They do not seem to be of the same quality at all." He is inclined to consider them as glandular structures. "These cells must, as a whole, be regarded as glandular. I know of no other term to apply to them, although they have no ducts and in many respects are out of form as glands." Black, therefore, emphatically contends that the epithelial cells occurring in the peridental membrane are of two kinds, unrelated to each other; that those derived from the epithelial root-sheath are being absorbed and disappear completely, a process which, he claims, may be observed and confirmed by anybody who will take the pains to study it properly; and that those which persist through life in the peridental membrane are not like the other cells, but are normal to this tissue and may have a glandular function. It is, however, not clear from his statements whether there have been as conclusive studies made by him or others of this second type of cells. We are not informed when these cells appear, whether they may coexist with the first type, or whether they present any differential histological features, and no suggestions are made as to their origin.

* Black, "A Work on Special Dental Pathology." Chicago, 1915.

Adloff* likewise insists on making a sharp distinction in the epithelial cells of the peridental membrane which it has been customary, since Malassez, to call as a whole *débris épithéliaux paradentaires*. These may be genetically all the same, but they differ greatly in their

the other hand, remnants of the epithelial sheath. The former are genuine embryonic structures, their function being limited to embryonic life. The latter continue to functionate until the growth of the root in length has been completed, *i.e.* during a considerable time of extra-

further development. There are, on the one hand, those buds and secondary outgrowths of the enamel ridge which are exceedingly frequent during the embryonic development of the human teeth in the various developmental stages, and on

uterine life, and being absorbed when this function is fulfilled; cells from this sheath are remnants of a used-up organ, hence they lack the growth-energy of the other type of cells when they become active again in a granuloma or a cyst.

Black's statement, that the epithelial cells which persist in the peridental membrane through life must be regarded as glandular, is not yet supported by any

Similar to preceding illustration.

proof; but it can hardly be denied that structures which, as he contends, are normal to the peridental membrane, and constant elements in so highly an important tissue, may have some physiological function to perform. Illustrations of these cell cords in Noyes' textbook, and casual remarks in the literature, hint at the possibility that they may be in some way connected functionally with the cementum. Noyes describes them as being surrounded by an extremely delicate basement membrane. "They lie very close to the surface of the cementum, winding in and out among the fibers. They anastomose and join with each other, forming a network, the meshes of which are comparatively close in the gingival portion and comparatively wide in the apical portion." (Fig. 1.) He calls attention to the observation that "The ends of the loop toward the cementum often show enlargements which in some cases apparently lie directly in contact with the cementum." (Figs. 2 and 3.) Astachoff,* who examined 98 specimens from jaws, also observed the close proximity of the epithelial "cell islands" to the cementum. In one case of a cyst he found them even in eroded depressions of the cementum. He writes of them, "They are similar to the odontoclasts, or they replace to some degree, as an epithelial sheath, the bundles and cells of the peridental membrane which are lacking here."

Dreuw and Rumpel† go still farther in claiming that "The epithelial nature of these cells is not yet indisputably established as hitherto generally believed. Investigations are still to be made to ascertain whether these cells are derived from the connective tissue cells proper, or from the endothelial, respectively perithelial cells, or whether they are to be brought in connection with the cementoblasts, which in their processes, nucleus, and protoplasm resemble in several respects the peculiar cell forms described by us."

† Dreuw and Rumpel, "Ueber eigentümliche Zellformen bei Zahngranulomen," *Virchow's Arch.*, 1910, cc, 89.

HERTWIG'S SHEATH.

It is, indeed, striking what a degree of differentiation cells of the connective tissue type may attain. The odontoblasts which are formed from the cells of the pulp, *i.e.* from connective tissue cells, are high columnar cells, and resemble much more epithelial cells than the cells in Malassez' *débris épithéliaux paradentaires*. It may be worth while to review some of the statements of embryologists concerning the structures from which these cells are considered to be derived. To Von Brunn* we owe the best description of the enamel organ and of the so-called epithelial root-sheath, which is frequently called after him "Brunn's sheath," but, as proposed by Brunn himself, more properly called Hertwig's sheath, Hertwig having described it first.

Von Brunn calls attention to the fact that in rats the summits of the crowns of the molars are free from enamel; immediately after the eruption of the teeth the dentin is already freely exposed on the outer surface. The incisors of rodents are provided with enamel only on the front surfaces; also the summits of these teeth are enamel-free at the time of eruption. The incisors of these animals have no roots. Yet at an earlier stage of development these teeth have a complete covering of enamel epithelium like other teeth. Tomes† also found that in the armadillo, whose teeth are absolutely free from enamel, the tooth anlage nevertheless begins with the formation of a complete enamel organ. In the eel and various fishes the enamel organ likewise extends very much farther than the final very small enamel cap.

The question naturally arises, What has the enamel epithelium to do in those places where subsequently no enamel is being developed? Von Brunn showed that its purpose is that of giving form to the tooth, and that the function of enamel formation is only an accessory one. He writes, "Its presence is evidently necessary in order to the odonto-

* Von Brunn, *loc. cit.*

† Tomes, quoted from Von Brunn.

blasts' being properly placed, namely, against its inner surface; it forms the matrix for the later dentin substance. When the odontoblasts are placed in the proper position, when the first dentin layer is formed and in this way the shape of the tooth secured, the enamel epithelium has played its part for this portion of the tooth; now the fixation and fastening of the tooth can begin, and the connective tissue performing this work may destroy the mold." "I must emphasize in particular," he states, "that the first odontoblasts are always found at some distance from the free border of the epithelial sheath, and that from this I draw the conclusion that the presence of the epithelial sheath is the *conditio sine qua non* for the formation and arrangement of the odontoblasts, and thus of the dentin itself."

Quite novel are the views which Fischer* holds in regard to the ultimate fate of the enamel epithelial sheath. He claims that this epithelium, after having fulfilled its mission of enamel formation, by no means is resorbed and disappears or forms the enamel cuticle, as believed by some authors, but it continues to differentiate and becomes again typical epithelium of the mucous membrane. As the crown of the tooth breaks through, the flanks of the persisting enamel epithelial sheath try to establish a communication with the proliferated external epithelium of the mucous membrane, after having sent forward short buds and plugs into the surrounding connective tissue. The cylindrical matrix of the youngest enamel epithelium gradually passes over into the older cubical cell form, while the layer of ameloblasts, which is still present at the time of the perforation of the tooth, exchanges its cylindrical form with the cubical only later. Co-operating with the external epithelium, it finally produces the tissue proliferation which forms the later papilla of the gingiva. He states that the

importance of this "return" of the enamel epithelium to the mother tissue, of this "new characteristic" of all epithelium involved in the development of the teeth, is particularly emphasized when we consider the activity of the epithelium from the phylogenetic standpoint.

The most primitive form of dentition consists in a bulging out or an evagination of the epidermis into which a papilla of mesodermal connective tissue pushes from beneath. In the lower jaw of the pike we find for the first time the tendency of the epithelium to grow downward or to invaginate into the mesodermal tissue as a tooth germ, but without ever losing the connection with the mother epithelium. In amphibia we have both simple epithelial evaginations and invaginations into the depth, which, however, always remain in continuity with the mucous membrane. In reptilia the line of teeth may separate completely from the epithelium of the jaw, leaving only a few rudiments.

In all higher vertebræ the epithelium forming the teeth is regularly being snared off from the mucous membrane for a definite time, but when its mission is fulfilled it is differentiated back into the mother tissue. Remnants of epithelium may, nevertheless, be left in the depth of the jaw and persist as indifferent cells. These correspond to Malassez' *débris épithéliaux paradentaires*. These are, however, not differently sized collections, scattered irregularly and independent of one another, as represented by Malassez and his followers, but constitute a large wide-meshed network, which is being formed as the cementoblasts break through an originally solid epithelial sheath. This epithelium wound like a net around the root, and which morphologically belongs to the epithelium of the mucous membrane, may have retained enough regenerative energy so that in a case of cyst formation it may line the cystic cavity.

Apparently Fischer stands alone with his view of a return of the epithelial cells to the mother tissue—morphologically and functionally like it.

Granting that the epithelial cords of

* Fischer, "Beiträge zum Durchbruch der bleibenden Zähne und der Resorption des Milchgebisses." *Anatomische Hefte*, 1909, xxxviii, 617.

the peridental membrane, in general, are remnants of Hertwig's sheath, it is still possible that there are other cells of an epithelial nature in this tissue, derived from other sources, *i.e.* the mucous mem-

fact that the papillary bodies of the gingival mucous membrane proliferate under the slightest provocation: the tips of these papillary extensions are easily snared off, and may be found as pearls

Longitudinal section through the gingivæ on the proximal side. *Ep.*, Epithelium lining the gingival space. *G.g.*, Gingival gland, so called. *D.*, Dentin. *N.*, Nasmyth's membrane. *Du.*, Duct-like structure from the epithelial cord seen at *E.c.* *Cm.*, Cementum separated from the dentin by decalcification.

brane of the mouth. Dependorf* and other writers have called attention to the

and nests in lower regions about the teeth. Noyes is not disinclined to regard as possible a downward extension of the squamous epithelium of the mucous membrane of the gingiva and the gingival space as the crown breaks through.

* Dependorf, "Zur Pathogenese der Zahnwurzelzysten," *D. Monatsschr. f. Zahnheilk.*, 1912, xxx, 809.

Indeed, his illustrations strikingly reveal the seeming continuation of the direction of such cords from the depth of the membrane to the mucous membrane. (Fig. 4.)

ORIGIN OF EPITHELIAL CELLS IN ROOT-CYSTS.

While by the majority of writers the theory is adhered to that the epithelial cells occurring in root-cysts and root granulomas originate from the cell cords within the peridental membrane, an entirely different view is held by Grawitz.* This author believes that epithelial cells lining cysts are always derived from the squamous epithelium of the mucous membrane of the mouth. Every cyst begins with abscess formation within the granulation tissue. Epithelization of the cavity does not take place unless the pus reaches the surface of the mucous membrane through a fistulous tract. If this does occur, the squamous epithelium of the mouth grows downward and covers the wall of the duct as well as that of the cystic cavity. A closed cyst is formed if the fistula heals after it has been lined. According to him only the genuine odontogenous cystomas are derived from embryonic enamel epithelium.

Adloff† and Schuster‡ cite cases which they believe speak in favor of such an origin. Schuster, however, believes that the epithelial invasion from the squamous epithelium of the mouth does not necessarily depend on the formation of a fistula. Distal portions of proliferated papillary bodies of the mucous membrane may be snared off by the connective tissue and remain as an epithelial cell nest in the peridental membrane, and give rise to an epithelial invasion of a granuloma or cyst. He points out that if cell remnants of the enamel organ are the origin of the epithelial cells in cysts and granulomas, the structure of this organ

should be found reproduced to some extent. This is strikingly the case in cystomas, while the epithelial cells in a root-cyst show a marked resemblance to those of the mucous membrane.

The majority of writers, however, consider as untenable the views held by Grawitz. Astachoff,* who examined specimens from 98 jaws with the teeth *in situ*, did not find a single case which might be used as proof of this theory. Dependorf† points out that the epithelium appears in the granuloma early, before a cavity formation sets in, and that in fresh melting-down processes in encapsulated granulomas the tendency of pus to break through is rarely observed; the encapsulated focus remains restricted and is soon surrounded by epithelial cell tracts.

Perthes‡ advances the following arguments in refutation of Grawitz' theory: (1) The occurrence of epithelium in completely solid granulomas excludes the supposition that it owes its existence to the lining of an abscess. (2) The free movability of the mucous membrane over the cyst and the absence of a fistulous tract speak against it. (3) From clinical experience it is observed that a root-cyst never develops from a chronic abscess with a fistula. (4) Growth of a cyst such as is observed could not be accounted for if there were a communication from the cyst to the oral cavity, since the content of the cyst would be poured out constantly or at intervals.

While there is still such division of opinion in regard to the origin of the epithelium in root-cysts, authors generally agree concerning the genesis of follicular cysts and cystomas. The former, although in form and growth very similar to the root-cysts, have some characteristic features which make the origin rather obvious; the location, the time of development, and the content speak for an embryonic starting-point, namely, a misplaced or malformed tooth anlage. As to the latter, we may, from their his-

tological structure, rightfully believe that the epithelium in these tumors is derived from the enamel organ, the structure of which is strikingly reproduced in the tumor tissue.

ETIOLOGY OF ROOT-CYSTS.

Root-cysts result from chronic inflammations of the peridental membrane. The first impulse is given by inflammatory changes of the connective tissue, which are due to various influences, mechanical and chemical, but chiefly bacterial. Moorehead, in his extensive clinical experiences, found root-cysts almost invariably to arise from infected tooth-roots. He calls this type "infection cyst," in order to emphasize the distinction from follicular cysts which develop in the absence of caries of the teeth and apparently are unrelated to infectious processes of any kind. Proell* considers the granulation tissue which is being formed as a measure of protection on the part of the tissue surrounding the tooth against bacterial invasion. The next phase is the effect of the granulation tissue on the epithelial cells in the peridental membrane, which are in a state of repose as long as the root membrane is perfectly healthy, but awake from their slumber when this is altered.

Partsch† has seen distinct changes take place in these epithelial cells under the influence of an inflammation of the connective tissue. Vascular loops formed in the course of hyperplastic changes push out toward the cell nests and force them to give up their globular form, so that they lie like a cap over the loops. Dependorf‡ believes he has seen the beginning proliferation of the resting epithelium. The former may occur before the formation of granulation tissue; the latter only sets in when this is present. Wherever degenerative processes occur

in the granulation tissue, the epithelium shows the tendency to surround and encapsulate such foci. This is the beginning of cyst formation. Strands grow out from this epithelial layer into the granulation tissue and encircle and snare off other regions which, being cut off from the surrounding tissue, are poorly nourished, and hence the tissue undergoes degenerative processes. When these are complete the epithelial barrier is also dissolved and the detritus added to the cystic content. Some authors are emphatic in stating that the cyst begins chiefly through participation of the connective tissue, others that it begins with degenerative processes in the epithelium.

The peculiar behavior of the connective tissue toward the epithelial cells and *vice versa* produces most varied and often very strange pictures, which have given rise to various comparisons. Proell likens it to a mucous polypus, which seizes an object with its two main arms and incorporates it; when the two arms have closed around an area of granulation tissue a cyst is being formed. Witzel* compares such region of proliferation to a bath sponge, the supporting scaffold of which is the epithelium, while granulation tissue fills the alveoli. Römer† speaks of "Epithelglocken," epithelial bells. Drenw and Rumpel lay stress on the islands of connective tissue marked off by the epithelial cells, which they call "Plasmominseln," inasmuch as they are filled with plasma cells.

As to the fluid which occupies the cyst, Fischer‡ believes it is due to mucinous softening of the surrounding connective tissue; a cyst fluid proper is formed which passes through the epithelial layer and fills a space lined with epithelial cells. Also an inflammatory

exudate may diffuse through the thin cellular wall, according to him. Partsch disputes the formation of a cyst by liquidation of the epithelial cells, as Dependorf claims. If this were the case we should find epithelial cells in some form of transition or degeneration within the cystic cavity; this, however, is never observed. He holds the view that fluid accumulates in the space between the root and the granuloma, and thus a cyst is formed. This is not admitted by others on the ground that under these conditions the bare root should be found in every cyst.

An examination of a number of cysts such as I have made during the past year is peculiarly fascinating on account of the great variety of the histological features which they present. No two cysts are alike. Certain elements appear in nearly all of them, such as epithelial cells and plasma cells, but chameleon-like they change their appearance continually, and with almost every specimen we find differences in the arrangement, the location, the amount present, the size, and the staining qualities. The alterations are sometimes so marked, the disguise so complete, that it is often extremely difficult, if not almost impossible, to identify them.

SOME FEATURES OF DENTAL CYSTS ABOUT WHICH LITTLE IS KNOWN.

Descriptions of the histology of dental cysts abound in the literature; I will therefore limit myself to reporting some features which are considered as being very rare or have scarcely been mentioned, and to pointing out others which have not been discussed at great length.

A cyst lined on the outer wall with epithelial cells is an extremely rare occurrence. Adloff* reported two such cases. In both, ciliated columnar, respectively cylindrical and squamous, epithelial cells were found; both had fistulae lined with cylindrical cells which passed over into the squamous epithelium or the outer wall. Proell† described a cyst

which was lined with ciliated epithelial cells on the inner and outer wall; there was no fistulous tract in his case. Both authors are of the opinion that these cells were derived from the lining of the maxillary sinus. According to Adloff, fistulae are present in all cysts at some time; the absence of one in Proell's case simply indicates that it had healed completely. Although he admits that the cells of the body in general retain with great persistence their specific properties, he considers the squamous and cubical cells in his two specimens as being derived from the same source, *i.e.* the ciliated cylindrical cells of the antrum, a transition having gradually taken place from the ciliated cylindrical to the squamous type.

Römer, who observed a cyst lined on the inside with ciliated and squamous epithelial cells, objects to this conception of a transition of one type of cells to another, and believes that, in addition to Malassez' epithelial remnants, aberrant epithelial germs of the antrum could be taken into account. It would seem that the possibility of such an origin cannot be absolutely denied in Adloff's cases. One of these was associated with some noteworthy peculiarities. In a girl sixteen years of age the upper first molar had three roots, to each of which a granuloma was attached; two of these were of the simple kind, the third was the cyst described by him. He admits that the epithelium in the two former, as in all granulomas, was derived from the epithelial remnants; in the last, he believes, it originated from the antrum, and he states that "Thus for the first time the proof has been given that an epithelization of a granuloma may take place from the outside." "It is very remarkable," he continues, "that squamous epithelium analogous to that of the mucous membrane of the mouth has never yet been demonstrated on the outer wall of a cyst."

From these considerations the questions arise as to why an outside lining is so extremely rare; whether a fistulous opening is necessary to invite a growing downward of the epithelium, or whether,

* Adloff, *loc. cit.*

† Proell, *loc. cit.*

in the few rare cases observed, the covering of the outside wall with epithelium

outer wall is lined with stratified squamous epithelium which is continued over

FIG. 5.

FIG. 6.

Columnar epithelial cells on the outer and inner walls of the cyst.

follows or precedes the lining of the duct. I have a cyst in my collection in which a cleft extending from the interior to the

the curved edges and on the outer surface for a distance, when it ceases entirely.

Another cyst, 5×7 mm. in diameter,

formed a complete closed sac with projections on the outside wall resembling the rootlets on a green onion or a radish. On microscopic examination the inner wall was found to be irregular from rounded papillary protuberances and throughout lined with epithelial cells. These often form a single layer resting on a basement membrane; they are almost round and a little separated one

that originally the entire inner wall was lined with ciliated columnar cells.

The larger part of the cyst wall consists of connective tissue in rather dense fibers. Sections through regions with outgrowths on the outer wall show that the latter are lined with cells like those covering the inner wall, except that they are not ciliated. (Fig. 6.) This lining is continued from these papillary exten-

FIG. 7.

Protuberances on the inner wall of the cyst; angiomatous in structure, and in the state of marked hyaline degeneration.

from another, so that they look like beads strung loosely together; or they have one or two short processes on the free surface, or become more oblong and even spindle-shaped and may be present in several rows. Finally we come to portions where we have ciliated high columnar epithelium which rests on a basement membrane, or it is the last row of a layer of epithelial cells, the innermost of which consists of nearly spherical cells. (Fig. 5.) In some places the layer of ciliated cells is detached *en bloc*, or the cells lie loosely scattered, leaving the impression

sions on the outer cyst wall proper for a short distance. There are no nests or strands of epithelial cells within the cyst wall, as otherwise is generally found. A trace of a fistulous duct is nowhere to be seen. It is noteworthy that the ciliated columnar cells sometimes rest on several rows of polyhedral or spherical cells, the latter resembling those of the lower strata of the squamous epithelial cells of the oral mucous membrane. Since a direct extension of the epithelium of the maxillary sinus on and into the cyst cannot be demonstrated in this case, aberrant

germs of this epithelium may be considered as the origin of the epithelial lining of the cyst.

VASCULAR CHANGES IN DENTAL CYSTS.

There are only brief remarks in published reports about the vascular changes in cysts. Because of unusual features

curious-looking structures are found which stand out conspicuously by reason of their form and coloring. They are homogeneous masses of most bizarre forms—flattened disks, bars, curved sausage-like or straight, round and oval structures, often winding in and out and resembling greatly enlarged renal glomeruli.

FIG. 8.

Similar to preceding illustration.

connected with such changes two other cysts of my collection may be described. One of these is a large cyst involving the right upper jaw which had destroyed the anterior wall of the maxillary sinus. The cyst wall was of uneven thickness. In its thinnest portion small round bead-like projections were seen on the inner surface with the naked eye. In microscopic sections through such areas the inner wall, as well as the protuberances, is lined with a layer of stratified epithelial cells which is rather narrow over the straight surface. Within the projections

A perceptible lumen is rarely found, but there is often a dark line in the center. (Figs. 7 and 8.) They are evidently newly formed capillary vessels (lymph or blood) which have undergone a wholesale hyaline degeneration, and in this process have swollen enormously and increased the bulging of the epithelial wall produced by the formation of these loops of vessels. Calcification is present here and there. In some places greatly enlarged epithelial cells are seen which also have undergone complete hyaline transformation. Occasionally there is a

FIG. 9.

Section through giant-cell fibro-sarcomatous tissue adjacent to the cyst. Giant cells in the immediate neighborhood of spaces.

FIG. 10.

* Intricate network of spaces, many containing blood corpuscles.

granular material in place of the homogeneous structures. All these changes are strictly limited to the rounded protuberances.

This cyst presented another interesting feature. Large areas, in regions where the tissue assumes the character of a tumor, are occupied by an intricate net-

other cyst associated with a giant-cell fibrosarcoma, which was removed from the lower jaw of a boy of eight years. The syncytial cells are here obviously formed from connective tissue cells and plasma cells. Besides the lancet-shaped spaces with sharply cut edges and corners we have here a system of larger and

FIG. 11.

Formation of syncytial masses about spaces in tissue adjacent to a cyst.

work of large spaces and slits, frequently containing blood. The borders are generally well cut, occasionally lined with cells resembling endothelial cells; more often a nearly homogeneous tissue forms the boundary line; frequently syncytial masses with numerous nuclei are leaning against the wall, and sometimes invading the lumen. (Fig. 11.)

Almost identical pictures of spaces, hyaline degeneration, and syncytium or giant-cell formation are present in an-

smaller spaces with irregular borders; the edges have a tendency to be bayed out and rounded off; frequently globular and club-shaped masses of a rich cellular fibrous tissue project into the lumen. (Fig. 9.) There is no blood in these spaces. Syncytial structures are rarely seen in the immediate neighborhood; there are numerous giant cells, but they remain at some distance. The tissue is frequently altered beyond recognition. The inner lining of squamous epi-

thelial cells is present only in fragments. How far the space formation may go is illustrated in another cyst. (Fig. 10.)

The giant cells and syncytial cell complexes occurring in cysts of the dental system, and particularly in epulis, offer the most favorable conditions for studies of their genesis and development. They present the greatest variability of structure and form. In the last two cysts which I described, the form of the polynuclear cell masses is such as to make the name syncytial masses seem more suitable. They follow the lines of the spaces, are more or less broad bands, or masses having one or two lateral processes or one end projecting into the lumen. They stand out conspicuously in the tissue by reason of their intense staining. (Fig. 11.) They sometimes assume unusual proportions. Quite different are the masses which are found in the so-called giant-cell fibroma or sarcoma. Here they have the more typical round form, and frequently are more faintly stained than the surrounding tissue. Giant or syn-

cytial cells of dental cysts and tumors develop from all sorts of cells. Their origin from endothelial cells of blood and lymph vessels is very apparent. In epulis the giant cells often have the form of capillaries, and the nuclei may be peripherally placed and form an entire circle. More often complete occlusion of the vessels has taken place and the whole structure appears transformed into a giant cell with a pearl-like arrangement of the nuclei. Other capillaries of such tissue may be filled with a grumous or entirely homogeneous material without nuclei. Besides endo- and perithelial cells, other cells, as fibroblasts, squamous epithelial cells, and plasma cells, may give rise to giant-cell formation. The development is often that of fusion of the protoplasm, and from all appearances frequently results from degenerative processes.*

* All of the material used in the above studies was obtained from the surgical clinic of Dr. F. B. Moorehead.

The Nature of Pericemental Abscesses upon Vital Teeth.

By Dr. MAURICE ROY, Paris, France,

PROFESSOR AT THE DENTAL SCHOOL OF PARIS. DENTIST TO THE HOSPITALS OF PARIS.

THE fact most frequently invoked to justify the analogy of pyorrhea alveolaris with the formation of gouty tophi is that of a rare form of the disease characterized by the formation of alveolar abscesses upon vital teeth, which in part evolve similarly to abscesses due to the death of the pulp. The teeth in question are living; the gum appears to be intact at the cervix of the teeth, and the abscesses appear to develop upon the middle portion of the root without other

apparent communication with the exterior than the fistula resulting from their opening upon the surface of the gum.

Burchard* says: "A tooth exhibits the symptoms of acute apical pericementitis; a bistoury passed into the apex of the swelling over the root may give vent to a glairy, mucus-like discharge, or, in

* H. H. Burchard, "Varieties of Dental Calculi," DENTAL COSMOS, 1898, vol. xl, p. 8.

some cases, pus flows. A further examination may reveal the loss of underlying alveolar wall; on exposing the root, which is partially denuded of pericementum in this area of denudation, the presence of a calculus is detected. The pulp responds to tests for its vitality, and the gum margin and marginal pericemental attachment appear to be intact."

Kirk* describes the observed symptoms as follows: "The clinical phenomena attending the evolution of this condition are in general those of other inflammations of the pericemental membrane, but modified somewhat as to their violence. A slight uneasiness about the root of the affected tooth is first felt, followed by increasing tenderness to percussion, a slight extrusion of the tooth from its alveolus, increasing pain of a dull, throbbing character, localized swelling which does not become diffused over a large area, no tendency to the infiltration of surrounding tissues, no burrowing of pus into adjacent territory, finally localization and pointing of the abscess and evacuation of the inflammatory products upon the gum surface at a point close to the inflammatory focus. The discharged contents differ from the pus of the usual dento-alveolar abscess of pulp infection, both as to quantity and general character, being relatively slight in amount and mucoid or glairy in appearance, sometimes streaked with blood, and not so yellowish as pus due to infection by pyogenic cocci. After evacuation of the abscess cavity the outlet usually heals spontaneously, and the disorder remains quiescent for a greater or less period, when a renewal of the outbreak may occur, with a tendency to repetition indefinitely until the tooth is finally lost through general necrosis of its retentive ligament, the pericementum."

In order to explain the formation of those abscesses whose nature hitherto has appeared to be very difficult to determine, a number of authors assume that it is a question of gouty tophi of calcium

urates, deposited upon the root through the medium of the circulation, and thereby causing an abscess by hematogenous infection. Kirk interprets these abscesses as the consequence of hematogenous infection of the pseudo-glands of Black.*

Having had occasion to observe some such cases whose pathogenesis is very obscure, and having been able to establish their real etiology with absolute clearness, it seems to me advisable to insist very particularly upon a point which to my knowledge has not yet been noted, and which reduces to *nil*, in the cases I have observed, the deductions in favor of gouty tophi.

Cases of this kind are very rare, and many experienced practitioners have never encountered them. Consequently the first case which I had an opportunity to observe upon an upper central incisor some fifteen years ago made a vivid impression upon my mind. Being unable to find any other plausible explanation, I was inclined to accept the belief in the reality of gouty tophi in the pericementum without communication of the alveolo-dental articulation with the exterior. Nevertheless my mind was not satisfied, and some years later having had occasion to observe a similar case, I examined and explored the tooth in question with the greatest attention, and was overjoyed to find the explanation of the fact which had so greatly puzzled me.

The patient was an arthritic man of sixty years whom I had long known, still

* [In the paper quoted by Dr. Roy I merely suggested as a possibility that pericemental abscesses might result from hematogenous infection. In a later paper¹ I called attention to Black's observation of the direct infection of the epithelial rests of the peridental membrane through the gingival tissues, an observation which clearly determines the modus of infection in pericemental abscess as well as in pyorrhea alveolaris, which, though differing in clinical expressions, are pathologically identical.—EDWARD C. KIRK.]

¹ E. C. Kirk, "The *Locus Minoris Resistentia* in Pyorrhea Alveolaris." DENTAL COSMOS, vol. lv, 1913, p. 577.

* E. C. Kirk, "Abscesses upon Teeth with Living Pulp," DENTAL COSMOS, 1898, vol. xl, p. 621.

possessing all his anterior teeth as well as his premolars. These teeth were firm, and showed only a few evidences of a mild pyorrhea in the region of two of the premolars, which nevertheless were still quite firm. This patient one day came to me with a vestibular abscess lying half a centimeter above the marginal border of the gum of an upper lateral incisor, an abscess absolutely analogous

I was about to accept this conclusion, in the absence of a better one, when, while carefully exploring the abscess with a fine probe through the small gingival fistula so that I might gain a better idea of its configuration, I perceived that this vestibular abscess encircled the approximal surface of the tooth, and appeared to extend backward toward the palate.

FIG. 1.

FIG. 2.

FIG. 1: Pyorrhea with pocket as commonly observed. A, Portion of the denuded root with calcarous deposits. B, Pyorrhea pocket.

FIG. 2: Pericemental abscess on a living tooth. A, Showing orifice made by the abscess, which does not communicate with the neck of the tooth at the gingival border, where the tissues are intact. B, Opening made by the pyorrhetic infection. A probe is introduced to show the opening into the pocket. C, Portion of the denuded root with calcarous deposits, showing the progress of the infection.

with those which currently are observed in the course of complications sequent to the death and putrefaction of the pulp. Yet the tooth incontestably had a vital pulp, as it responded to thermal stimuli very clearly, and there existed no apparent communication between the abscess and the marginal part of the gum. The tooth was not loose. The conclusion then seemed unavoidable that this was a question of a pericemental abscess of gouty origin without demonstrable communication of the alveolo-dental articulation with the exterior.

I then examined this region with closer attention. On this side [palatal] there appeared to be no obvious lesion. The gum around the tooth appeared healthy, there was no recession, no suppuration, but what was my surprise, in passing my probe to the palatine region of the neck of the tooth to the point diametrically opposite to the seat of the abscess, to feel my probe fall into a narrow but deep pocket communicating with the threshold of the vestibular abscess along the middle third of the approximal face of the root, a communication

which I could easily establish with a fine probe.

This case was, then, contrary to all first impressions, a question of a pyorrhetic abscess analogous to those we frequently have occasion to observe, having its origin in a pocket opening to the exterior, but discharging at a point some distance from the pyorrhetic pocket.

It only remained to establish the reasons for this peculiar development of the abscess. These reasons I found in the occlusion of the teeth of my patient. His maxillary incisors completely covered those of the mandible, which latter just impinged upon the palatine mucosa, exactly at the neck of the lateral incisor and at the point where the opening of the pyorrhetic pocket was located, thereby forcing back the mucosa upon the orifice of the pocket. Because of this condition the products of infection and decomposition contained in the pocket were prevented from easy exit by its natural orifice. On the contrary, the masticatory movements forced these products more deeply into the pocket, and they sought discharge at some distant point of least resistance, *i.e.* in the vestibular region.

By establishing this fact the condition of the first patient was explicable to my satisfaction. I had been unable to recognize the true origin of that ab-

scess because, as I remember distinctly, the patient had presented just as marked an overbite of the maxillary incisors beyond the mandibular, and the same pathogenic conditions had been present to determine those phenomena whose true origin I had failed to recognize. Since then I have had occasion to observe two other similar cases, one with my *confrère* V. E. Miégevillé of Paris. Every case of pericemental abscess upon vital teeth which has come to my attention has occurred in patients presenting such an overbite.

Naturally it is impossible to prove that every case mentioned in the literature had an origin identical with that which I have just reported, but these facts will in the future necessitate great reserve before asserting the existence of an abscess of tophic origin upon a vital tooth independent of gingival infection.

I am convinced that if the practitioner be willing to institute a most minute investigation in all cases of so-called pericemental tophic abscesses upon vital teeth, he will find what I have found, and will acknowledge in principle that pericemental abscesses upon vital teeth are pyorrhetic abscesses formed in a serpiginous pocket whose cervical opening is not recognized because of its location at a point some distance from the gingival abscess.

The Pathology, Etiology, and Treatment of Pyorrhea.

By ARTHUR H. MERRITT, D.D.S., New York, N. Y.

(Read before the Academy of Stomatology of Philadelphia, April 18, 1918.)

PYORRHEA alveolaris is primarily a disease of the investing tissues of the teeth, that is, the gums, the gingiva, the alveolar process, the cementum, and the pericementum. It may be defined as a progressive resorption of the alveolar process and pericementum, with a coincident inflammation and recession of the gums and the formation of pockets around the roots of affected teeth. It begins at the gingival border and progresses slowly toward the apex of the root, resulting in the complete destruction of the alveolar process and pericementum, with eventual loss of the teeth unless arrested by treatment. Some of the phenomena attending its progress are gingival inflammation, solution of continuity in the floor of the subgingival space, absorption of the alveolar process, pocket formation, recession of gums, suppurative infection, sensitiveness to thermal shock, separation, elongation, and loosening of teeth. Of these, the first to manifest itself is gingival inflammation induced by various causes, the most common of which is uncleanness of the mouth. A careful study of the gingiva shows it to be an extension from the gum, surrounding and closely hugging the cervical enamel, to the height of 2 or 3 millimeters. Histologically it differs from the gum tissue, being covered with a dense pavement epithelium and receiving the gingival group from the pericementum. It also differs within itself, the septal gingiva being quite unlike the labial and lingual gingiva, less dense and less resistant. Between it and the cervical enamel is a space known as the subgingival

space, the floor of which is bounded by the alveolar process and cementum.

It is at this point that the first lesion in pyorrhea alveolaris occurs. Irritation of the gingiva causes inflammation, which, if long enough continued, is conveyed through the gingival group of pericemental fibers to the pericementum, eventually causing a break in the floor of the subgingival space. Coincident with the break, the cementum, pericementum, and alveolar process are exposed to the destructive forces of irritation and infection. A phenomenon known as osteoclasia is set up in the alveolar process, which is slowly resorbed. The rapidity with which this occurs will depend on several factors—the thickness of the bone, the resistance of the patient, the cleanliness or uncleanness of the mouth, etc.

As a rule the progress is slow, often years elapsing between the initial gingival irritation and final exfoliation of the tooth. Coincident with this process, and keeping pace with it, is destruction of the pericementum. The fibers of this membrane in health attach themselves on the one side into the substance of the cementum, and crossing the space are attached to the alveolar bone. Upon the surface of the cementum and attached to it are remnants of the necrotic membrane. Covering this and extending more or less over the denuded cementum is a calculary deposit brought about through the pathological changes taking place in these tissues. The destruction of alveolar process and pericementum is followed by shrinkage and recession of the gums, though this recession never

keeps pace with the destructive process taking place in the subjacent tissues. The result is the formation of a pocket, bounded at one point by the extreme limit of bone necrosis, and at the other by the margin of the gum. Between these two points there may be and often is a pocket of considerable depth, depending upon the amount of bone loss and gum recession.

Laterally these pockets are bounded on the one side by the overlying soft tissues and on the other by the cementum with its investment of necrotic pericementum and calculary deposit. Into these pockets, even in their earliest beginnings, the bacterial flora of the mouth finds its way. These organisms are purely secondary invaders, having no direct etiological relationship to the disease. Comparative studies of the bacterial flora of these pockets show that they do not differ qualitatively from that of the normal mouth. There is, as might be expected, great quantitative difference, this being explained by the fact that these conditions are more favorable to bacterial growth and development than is the healthy mouth. This flora is a mixed infection of great complexity.

The pus-producing cocci are present in large numbers, and in every known strain. Spirochetes, fusiform bacilli, and organisms of unknown types are also present, as is the amoeba. There is no evidence that any of these sustain a direct causal relationship to the disease. They do, however, give rise to one of its characteristic symptoms of pus, for without infection there would be no discharge from these pockets. It is true, there are cases in which there seems to be no pus. This does not necessarily mean that there is none. This apparent absence may be due to shallow or wide open pockets, as a result of which the pus is washed away by the oral secretions as rapidly as it is formed, or it may be due to an inactive phagocytosis, or both. That bacterial growth is less in such cases, or that it is less pernicious in its influence, seems improbable. These bacteria give rise also to metastatic infections of the gravest import, in many

instances contributing to the ill health and inefficiency of the patient, and not infrequently are the indirect cause of death. About one thing there can be no doubt, namely, their potentiality for evil is an inherent quality dependent only for its exercise upon the virulence of the organisms and the resistance of the host.

This, briefly, is a picture of some of the pathological changes taking place in the investing tissues of the teeth as a result of the initiation and development of pyorrhea alveolaris—changes which, unless observed in their earliest beginnings, will eventuate in the loss of the teeth, with possible secondary infections of a serious nature.

ETIOLOGICAL FACTORS IN PYORRHEA.

For convenience sake, the etiological factors of pyorrhea may be divided into two groups, predisposing and exciting. Such a division is necessarily an arbitrary one, since it is impossible in all cases to draw an accurate line between the two, as under certain conditions a single factor may at once predispose and excite. An unsanitary mouth may be said to be an example of this kind. It is desirable, therefore, that every case presenting for treatment be carefully studied with a view to determining as accurately as possible the factors which have caused it; for no case can be intelligently treated in which there is not a clear comprehension of all the forces which have entered into its causation. It must be obvious that unless these are recognized and removed, all efforts at correcting the pathological changes which have taken place in the tissues themselves will be more or less futile.

PREDISPOSING CAUSES.

Among the more common predisposing causes may be mentioned systemic diseases, localized malnutrition, frail bony investment of the teeth, and occlusal trauma. It should be remembered, however, that it is not by any one of these conditions that pyorrhea is caused,

but by a combination of them, including those in the exciting group.

SYSTEMIC DISEASES.

Little of an exact nature is known regarding the relationship between certain diseases, such as tuberculosis, diabetes, syphilis, etc., and pyorrhea. That diseases such as these, especially in advanced stages, may so impair body resistance as to predispose to pyorrhea, there can be little doubt; that they necessarily do so, or that they express themselves in characteristic types of pyorrhea, is improbable. Even in those cases in which the defensive forces of the body are seriously impaired by the progress of the diseases mentioned, it is doubtful whether in most instances they would be sufficiently potent to actually cause pyorrhea in the absence of exciting causes. If this be true—and it seems probable—guarding against the development of localized exciting causes by increased care should be sufficient to render non-operative any possible relationship which might exist.

LOCALIZED MALNUTRITION.

Largely as a result of modern habits of life, together with the end-organ nature of the circulation in the investing tissues of the teeth, they are peculiarly susceptible to trophic changes, by which is meant a loss of nutritional balance. The use of prepared foods, entailing little or no real exercise of the organs of mastication, probably has more to do with development of disease in these tissues than has the nature of the circulation, which under normal conditions is sufficient to insure against disease. The inefficient use of the toothbrush in no small measure contributes to this condition, for as a matter of fact, it should through artificial exercise supply, in part at least, the needed stimulation in these tissues. The result is poorly nourished gums, which bleed on the slightest provocation, a fact which causes the patient to relax in his efforts at tooth-brushing, contributing thereby to the very cause which he hopes to correct.

FRAIL BONY SUPPORT.

The absence of normal exercise above referred to, together with hereditary influence, has not only resulted in poorly nourished tissues, but as might be expected under such conditions, in tissues that are subnormal in size. This will be obvious to anyone with even limited clinical experience in the treatment of these conditions, but especially impressive is it when a comparative study is made of the maxillary bones of ancient skulls with those of modern life. Such study will reveal the fact that these bones have not only undergone marked diminution in size, but in the thickness of the alveolar bone. Instead of being thick and dense at the gingival border, the alveolar bone will be found to have atrophied to a point of extreme tenuity.

This difference in thickness prevails, moreover, between individuals and between races. This is a matter of common observation, and will explain in part why it is that the incidence of pyorrhea is greater among those individuals and races with frail bony investment of their teeth. It will require no stretch of the imagination to understand why it is that teeth so supported, when subjected to adverse conditions such as prevail in poorly nourished tissues, occlusal trauma, gingival irritation, etc., more easily succumb to the destructive influence of pyorrhea than do those more favorably environed.

TRAUMATIC OCCLUSION.

Until recently few, if any, realized the relationship which exists between occlusal maladjustment of the teeth and the destructive processes which involve their supporting tissues. For a considerable time there has existed a vague notion that in some way malocclusion (using the term in the Angle sense) was an etiological factor in pyorrhea, but that pathological changes might occur in the dental investment about teeth with so-called normal occlusion, and did so frequently as a result of occlusal maladjustment, no one realized. As a matter of fact it is not a question of tooth

regularity or irregularity, but of harmony or its lack in the occlusal relations of inclined planes of opposing teeth when brought into contact. This cannot be made too plain, for it is still not clear to many that malocclusion and traumatic occlusion are quite different conditions, which may be wholly unrelated, and either may exist without the other. It is probably true, however, that other things being equal, which they rarely are, malocclusion predisposes to traumatic occlusion, and thus predisposes to pyorrhea.

Teeth may be said to be in traumatic occlusion when under the force of mastication they are driven outside of their normal limits of motion to such an extent as, under certain conditions, such as poorly nourished tissues, frail osseous support, etc., to actually induce pathological changes in the pericementum and alveolar process. There are few cases of pyorrhea in which this is not a factor to be seriously reckoned with, especially in advanced cases, where if it were not a large etiological factor, it exists as one prejudicial to recovery. Careful study of every case will be required to determine the part which abnormal motion plays in its etiology and progress. This should include observation of the occlusal relations of every tooth, number and locations of missing teeth, use of thin carbon paper, placing of the finger lightly on suspected teeth, and instructing the patient to bring the teeth into occlusion, etc.

EXCITING CAUSES.

When we come to a consideration of the exciting causes of pyorrhea we may epitomize our present knowledge by saying that anything which induces irritation of the gingiva must be regarded as a potential exciting cause, if long enough continued. The fact should never be lost sight of that pyorrhea always begins as gingival irritation, followed by solution of continuity in the floor of the subgingival space, with consequent exposure of the subjacent tissues to irritation and infection. The ease

and rapidity with which this occurs will depend upon factors which have already been considered.

MOUTH HYGIENE.

One of the prolific causes of gingival irritation is uncleanness of the oral cavity, for the laity, in spite of the oral hygiene propaganda, have not yet learned the lesson of mouth cleanliness, at least they have not learned how to achieve it. Until they have learned this, and until there is a standardized method of tooth-brushing established on correct principles that is at once simple, efficient, and stimulating, there can be no hope of successfully preventing lesions of the investing tissues of the teeth, with all their disastrous sequelæ.

FAULTY APPROXIMAL CONTACT POINTS.

Another prolific cause of gingival irritation is faulty contact points. No examination of the mouth is complete which does not include a careful study of every approximal space, and no treatment will be wholly effective which does not include correction of faulty contact points when needed. With the introduction of the cast gold inlay this has been made possible to a degree before unattainable. The shell and band crowns have been, and still are, especial offenders in this class, inducing as they do in so many instances a chronic suppurative gingivitis which will continue as long as the crown remains in contact with the gingiva. Overhanging edges of fillings, especially amalgam and gutta-percha, also fall within this class. These should also be removed, and proper restorations made. Few, unless they are making a specialty of periodontia, realize how large a part faulty restorations play in gingival irritation and pyorrhea.

TREATMENT OF PYORRHEA.

In the treatment of pyorrhea an effort should always be made to determine what have been the etiological factors in the case under consideration, and as far

as possible they should be removed. Correction of occlusion, good root surgery, and the establishment and maintenance of a high order of mouth hygiene are fundamental to success in every case. Pyorrhea is a curable disease, just as tuberculosis is a curable disease, but just as patients suffering from the latter do not always recover, so patients affected with pyorrhea may not always be cured; and for the reason that in some way, which it may not be easy to explain, the conditions essential to success have not been complied with. For one thing a most exacting technique is essential. Even when this is observed complete success does not always attend one's efforts, simply because of the exceeding difficulty of meeting all the conditions. Moreover, because of a combination of circumstances which it may be difficult, if not impossible, in a given case to control, good results are not always achieved even in cases in which the prognosis seems promising.

One difficulty which attends all these cases is that to a certain extent one is dependent upon the co-operation of the patient for success. This co-operation is not always obtained, and results will be modified in consequence. The difficulty in restoring lost teeth in such a way as to prevent undue strain upon those remaining, of correcting the occlusion to insure against further trauma, and of maintaining a high order of mouth hygiene, is such that under the most favorable circumstances the results are not always all that could be desired. This being true, it is not difficult to understand why the perfunctory treatment so often given these cases is not successful, or why it is that those having failed as a result of such treatment should be pessimistic, or why they should ascribe their failures not to the inefficiency of their treatment, but to the incurable nature of the disease. Such treatment never has cured pyorrhea, and never will.

TRAUMATIC OCCLUSION.

Clinical studies of teeth in traumatic occlusion show that under the force of

mastication they are constantly being driven outside their normal limits of motion. A finger placed lightly on such a tooth will readily detect this shock when the teeth are brought into occlusion. The first change, as seen roentgenographically, is a thickening of the pericementum. This disturbance will in turn, if long enough continued, be communicated to the alveolar process, and be represented by a slight rarefaction about the lateral walls of the root, and occasionally by resorption at the apical end, simulating a blind abscess, and often mistaken for such even by careful observers. All these changes may take place about a tooth in traumatic occlusion without solution of continuity at the gingival margins. Add to these conditions gingival irritation, and we have the three most important factors in pyorrhea—local malnutrition, traumatic occlusion, and gingival irritation.

Treatment consists in the correction of occlusion and the establishment of normal nutrition in the investing tissues of the teeth. The correction may be achieved in most instances by judicious grinding of the occlusal planes of all teeth in traumatic occlusion. This is best done by the use of small carborundum stones, simply grinding the contact points as shown by thin carbon paper. When this is properly done, no mutilation results, the teeth are rendered more esthetic in appearance, and the patient more comfortable. Care should be exercised, however, against indiscriminate grinding.

It should be kept clearly in mind in these cases that traumatic occlusion, local malnutrition, and gingival irritation are usually associated, and that intelligent treatment requires that each be considered in its proper relation. It is possible for the teeth to be, and one frequently sees them, in traumatic occlusion, producing no pathological changes in their investing tissues, simply because these tissues happen to be well nourished. Right here is the controlling factor, and the wise clinician is he whose efforts are directed toward building up these forces of resistance. The correc-

tion, therefore, of anything more than the more obvious faults of occlusion should wait upon treatment directed toward the correction of gingival irritation and local malnutrition. When this is done excessive grinding will not be necessary.

ROOT SURGERY.

The most important factor in the treatment of pyorrhea and the most difficult to achieve is good root surgery. This requires the removal not only of all calcareous deposits upon the exposed surface of the cementum, but the complete removal also of the necrotic pericementum, permitting thereby physiological contact between the vital cells of the cementum and the overlying soft tissues. Also the root must be left smooth, care being exercised not to plane through into the dentin. The instruments in most general use are of two types, curets and planes, both of various shapes and angles. It is a matter of indifference which type is employed, so long as the conditions essential to success are met. When this is done reattachment takes place, pockets are obliterated, new bone is deposited about the roots, the teeth become firm, and health is re-established in these tissues, though complete restoration to previous conditions may not occur: in advanced cases there will probably be gum recession.

I realize that it has been asserted and is still believed by many that "suppurative detachments of the periodontal membrane are permanent detachments": that since the cementum is a specialized tissue without independent circulatory system, it automatically becomes a dead tissue when, through suppurative infections, it loses its pericemental investment. This not true. The fact that reattachment, with all that it implies, takes place in a single instance disproves any such supposition. As a matter of fact, such reattachment takes place, *as a rule*, in the hands of the skilful periodontist. No other result is regarded by him as a cure.

The explanation of this difference of

opinion is to be found in the fact that one group has met the conditions requisite to success, and the other has not. Reattachment will not take place about teeth on which poor root surgery has been practiced. This cannot be made too emphatic. Inasmuch as it is not easy to discriminate between that which is skilfully done and that which is not, it is not surprising that certain observers unfamiliar with present-day requirements should have ascribed their failures to "pus-soaked cementum," when in reality it was due to faulty technique. Reattachment can only take place through the agency of vitally active cementoblasts, which implies vital cementum. The fact that reattachment never takes place about non-vital teeth that have become septic indicates that in some way not as yet understood the pulp is the controlling factor in the vitality of the cementum. The absurdity, therefore, of destroying the pulps of teeth in the treatment of pyorrhea, as advocated by some, must be obvious.

POST-OPERATIVE TREATMENT OF PYORRHEA.

The average person, even among those who make some pretension to mouth hygiene, does not give intelligent care to his mouth, and does not keep his teeth clean. This is due to ignorance, to inadequate instruments, by which are meant toothbrushes, dentifrices, silk tape, porte-polishers, etc., and to inefficiency in their use. All this must be corrected in the post-operative treatment of pyorrhea. Most cases which present for treatment would never have occurred had proper care been observed on the part of the patient and family dentist, and unless these conditions are corrected failure is bound to follow the most skilful treatment.

The importance, therefore, of intelligent home care will be obvious. Ignorance on the part of the patient as to what constitutes such care is the first difficulty to be overcome. Unfortunately, there is no unanimity of opinion among dentists on this point. There is

no standardized method of tooth-brushing, and until there is one based on correct principles, confusion is bound to prevail. In any method, the first requisite is that it shall be simple. There are many people so lacking in manual dexterity that they will never learn a complicated system and practice it efficiently. Secondly, it must be effective; the teeth and mouth must be thoroughly cleansed. Thirdly, it must stimulate the investing tissues of the teeth. This is absolutely essential, and can only be done by a most vigorous brushing of the gums, as high up and low down as the cheeks, lips, tongue, and hard palate will permit, and lastly, it must not injure teeth or gums.

THE AUTHOR'S METHOD OF BRUSHING THE TEETH.

I shall outline for your consideration a method which I have found most satisfactory in my practice, and which is at once simple, effective, stimulating, and free from any injurious effects. The first essential is a small toothbrush of good quality, with the tufts sufficiently separated to make them flexible. Having been charged with a dentifrice, it should be placed high up on the gums in the posterior molar region, and swept rapidly up and down as far as the cheeks and lips will permit, gradually passing in this way from one molar region to the other. Not less than thirty seconds should be given to these surfaces of the teeth. The mouth should then be opened and the brush placed against the gums at the lingual surface of the last lower molar, and the motion repeated, care being observed to brush the gums vigorously. In the molar region the stroke will be more or less horizontal, becoming vertical as it approaches the median line. This procedure should in turn be repeated on the lingual surfaces of the upper teeth. The bucco-distal surface of third molars can be reached by a semi-circular motion with the mouth partially closed to relax the muscles in this region. The tongue should then be extended and thoroughly brushed.

The whole operation should be repeated night and morning, and occupy not less than two minutes. After meals particles of food should be removed with waxed silk or quills, and about thirty seconds spent in brushing the teeth and gums. In any case where for some reason it is thought best, this can be often repeated. Such cases will present themselves. When this method of brushing is properly followed the mouth will be kept clean, no injury to teeth or gums will result, and the whole operation will be followed by a sense of glow in the gums, of which one will be conscious for an hour or more.

There is an impression abroad that straight up-and-down brushing will injure the gums, and that if long enough persisted in it will cause recession. The fact that this is not so may be explained by the histological arrangement in the gingivæ of the fibers from the pericementum, and by the thick pavement epithelium which covers them. Nature seems to have made provision against vertical stress, inasmuch as this is the force to which the gingivæ are constantly being subjected in mastication. The same force applied horizontally with a brush will destroy the gingival attachment, and inevitably lead to permanent recession. My own teeth, which have never been cleaned by a dentist and which have been brushed in an up-and-down direction for more than twenty years, show no abrasion or gingival irritation, and are clean. I have obtained the same results in the mouths of my patients wherever the method has been fairly tried. Its chief value lies in the fact that the method is so simple that anyone can readily learn to employ it, and most important of all, it is stimulating to the investing tissues of the teeth through the vigorous massage effect produced.

There is no feature of the post-operative treatment of pyorrhea more important than proper brushing of the teeth. This makes it necessary that patients be instructed with great care, and be fully impressed with their responsibility in the final results. They should be pro-

vided with proper brushes, their use being demonstrated in one's own mouth. Caution against too vigorous brushing at first will be necessary, lest friction on tender gums result in sore mouths. They should also be taught the use of waxed silk tape, and in some instances porte-polishers. Dentifrices of known composition should be provided for their abrasive quality; they possess no therapeutic action worthy of consideration. Mouthwashes may be used during treat-

ment for their soothing and healing effect; their continued use is unnecessary. Dependence is to be placed upon well-nourished and highly resistant tissues, not upon mouth-washes, medicated tooth-pastes, or the thousand-and-one nostrums which are being advocated.

Surgical Correction of a Double Hare-lip, Alveolar Cleft, and Cleft of Hard and Soft Palate.

By M. N. FEDERSPIEL, B.Sc., D.D.S., M.D., Milwaukee, Wis.,

PROFESSOR OF ORAL SURGERY, MARQUETTE UNIVERSITY DENTAL SCHOOL, MILWAUKEE, WIS.

THE patient, W. V. M., a male of four years, was an American born (white), weighing 34 lb. He was suffering from hare-lip and cleft palate.

History. One of twins, youngest of family of five; three older children and twin brother normal. No history of hare-lip or cleft palate among relatives on father's side; mother, however, being left an orphan in early childhood, does not remember her relatives.

The patient was strong at birth, and suffered no children's diseases excepting cholera infantum; was bottle-fed, always healthy and playful, and is now a well-developed child.

Examination. A double cleft of the upper lip extended into each nostril (see Fig. 1). A double alveolar cleft (see Fig. 2) was present, and a very marked protruding premaxillary bone holding two central incisors. (See Fig. 3.) The clefts of the alveolar process united with a medium-sized cleft of the hard and soft palate.

The mouth was fair as to cleanliness, the mucous membrane normal, and there

was no visible gingivitis or pericementitis. There were occlusal cavities in the lower second deciduous molars. The tonsils were normal, and no enlarged adenoids were present.

The patient was referred to Marquette University oral surgery clinic, Trinity Hospital, April 2, 1918, and prepared to be operated upon April 4th.

The urine and blood were normal. The patient was admitted to the operating-room at 7.45 A.M., and put under ether anesthesia. Under the anesthetic, further examination revealed that the protruding mass contained two central incisors which were tipped lingually. In this case, the lateral halves of the upper jaw were very well developed, and held the following well-developed deciduous teeth, 5432 | 2345, the occlusion of these being in normal mesio-distal relation.

The shifting of the protruding mass distally would not permit the closing of the alveolar cleft, for the mass in itself was too narrow to complete the normal upper arch, and the anterior wall of the bone was found to be badly developed.

FIG. 1.

Showing the front view of a double hare-lip. The cleft on the right side cannot be seen because of the protruding os incisivum obstructing the view. See Fig. 2.

FIG. 2.

Palatal view showing the complete cleft.

The mass was ovoid in shape and stunted in growth, evidently due to the absence of lateral support and failure to functionate.

In many cases of double alveolar cleft we find that the os incisivum is usually larger than the mass here described, forming a projecting tubercle, covered by smooth mucous membrane on the inner side, with the central portion of the

FIG. 3.

Side view showing the prominence of the os incisivum attached to the tip of the nose.

upper lip attached anteriorly. In an infant it should contain the tooth buds of the temporary and permanent central incisors, arranged in pairs, one above the other. This type of oral deformity is of the most pronounced kind, yet, when operated upon at an early age (from one to three months), and the os incisivum is well developed and large enough to close the alveolar cleft, I perform a submucous resection and cut the vomer. This permits the forcing of the displaced os incisivum backward so as to form a

satisfactory alveolar arch. The bone is then held in its new position by passing

FIG. 4.

FIG. 5.

a silver wire through the vomer as illustrated in Figs. 4, 5, and 6. In this way

FIG. 6

there is no injury done to the unerupted teeth. The borders of the alveolar cleft can then be cauterized several days later

This, however, could not be done in this case, since the os incisivum was undeveloped, holding two centrals which were tipped lingually. Therefore, in view of the condition, Dr. A. Trigg, a prosthodontist, and I decided that it would be good surgery and far more practical to remove the protruding mass and prepare the vomer bone to act as a good base for

FIG. 7.

the artificial restoration of two central incisors. This was done under the following technique:

The muco-periosteal flap on the labial and lingual surfaces was dissected, and the mass, containing the two deciduous centrals and the tooth buds of the permanent centrals, was removed. (See Fig. 7.) The flaps of the soft tissues were

FIG. 8.

FIG. 11.

Side view under same conditions.

then brought in contact and stitched on to the lateral halves of the jawbone so as to close the anterior portion of the floor of the nose. There then remained only the cleft of the hard and soft palates. Following this operation, the double cleft of the lip was closed by bringing in contact the soft tissues which covered the protruding mass and the borders of the lip on each side. The vermilion surfaces were carefully joined, and the alæ of the nose were turned inward so as to give the boy the proper-shaped nostrils. Paraffin silk was used to suture the soft tissues. (See Figs. 8 and 9.)

The wound was kept clean by gently washing it with boric acid solution. On the eighth day the stitches were removed (see Figs. 10 and 11), and the lad was then able to functionate his lip normally.

In about six months or longer the cleft of hard and soft palates will be closed. In order to keep the space open between the lateral incisors, an orthodontic retaining wire will be fitted and adjusted so as to insure this space, which, at a later date, can be restored with a well-fitted anchor denture holding two centrals.

413 WELLS BUILDING.

The Rôle of Sepsis and of Antisepsis in Medicine.

By WILLIAM HUNTER, M.D.Edin., F.R.C.P.Lond.,

PHYSICIAN AND LECTURER ON PATHOLOGY TO THE CHARING CROSS HOSPITAL, LONDON;
PHYSICIAN TO THE LONDON FEVER HOSPITAL.

(Delivered at the opening of the session of the Faculty of Medicine of McGill University, Montreal, on October 3, 1910.)*

[An introductory section of the Address dealt with the Objects of Medical Education.]

MEDICAL SEPSIS AND MEDICAL ANTISEPSIS.

AFTER these prefatory remarks regarding the objects of your present studies, I pass on to the subject which I have selected as the special theme on which I desire to address you today. That theme is the great part played by septic infection—prevalent, potent, easily observed, and accessible to treatment, nevertheless continuously overlooked and neglected—as an important cause and complication of a whole range of medical diseases. I have selected it not only because of its great practical importance to you in your med-

ical work in after-life, but also because the story of its recognition as a great factor in causing disease illustrates in a striking way the truth of what I have just said about the importance of small things in medicine—their observation and interpretation.

For it was while seeking to throw light on the origin and meaning of a piece of blood pigment present in an organ in the first case I ever examined for curiosity's sake, that I stumbled upon the chief subject and interest of my life's work, namely, that of anemia. And it was while observing as fully as I could all the features of the first case of anemia which I ever studied clinically that I came upon the curious facts that ultimately led me to recognize the impor-

* Published originally in the *Lancet*, London, January 14, 1911.

tance of sepsis in medicine not only in producing anemia, but also many other medical affections.

I spent some five years (1885-90) in experimental and pathological work in trying to explain the meaning of that piece of pigment, and some ten years (1890-'00) in trying to explain the features presented by that one clinical case. And *then I saw*, but not till then, what I have since endeavored to describe in various papers from 1900 onward up to the present time regarding the rôle of sepsis in medicine and the importance of oral sepsis as its chief cause.

I desire now to draw your attention to the great province concerned with the action of septic infection in medicine as one deserving your attention as much as sepsis in the great domain of surgery. Like the great Northwest Territories of your own land, this province of sepsis in medicine has been with us all the time, awaiting only a fitting recognition and exploitation of its great resources. It is as yet but sparsely populated; workers and settlers in it are but few, though they have been steadily drifting into it during the last ten years, first one by one, and more recently by scores and hundreds, and already many of these have sent back encouraging and even glowing accounts of its resources. But the field is so large and the work in it is so great that its resources will not be fully exploited till the workers in it include the whole profession, prepared, if necessary, to identify themselves with it by taking the name of this great province of their work. For like many of your territories, it has remained until now without even a definite name. That name I propose now to give it, so that even if you pass it by and are not attracted by its prospects, you will at least from henceforth know what portion of the great domain of medicine is meant by it.

Time was, and I am old enough to recall it, when the greatest honor that could be paid a surgeon was to term him a brilliant operator, and to expatiate upon the rapidity with which he could carry out a particular operation. Time is, and long has been, when the title

which a surgeon is proudest of is that of an "antiseptic surgeon." Possessing the knowledge, the training, and the experience that entitle him to that name, he knows that it is possible for him to become a successful surgeon, he is a worker in the field of "antiseptic surgery."

The time, in my opinion, has come—or if not already come, is fast approaching—when the title of "antiseptic physician" will become equally distinctive of a good doctor; when it will be equally honored and honorable as that of "antiseptic surgeon" now in the case of the surgeon; when the knowledge and outlook which it implies in regard to the importance of sepsis in medicine will be deemed one of the highest qualifications which a good doctor could possess; when, in short, "antiseptic medicine," the fight against sepsis in medicine, will come to have as distinct a meaning in relation to sepsis in medicine as "antiseptic surgery" has in relation to sepsis in surgery; when a knowledge of the principles and practice of "antiseptic medicine" will be deemed as essential and necessary to the physician as a knowledge of the principles and practice of antiseptic surgery is now essential to the surgeon. What these principles are it will be the purpose of this address to bring to your notice. They are deeply rooted in the knowledge and experience which it is the purpose of your present studies to give you.

PRINCIPLES OF ANTISEPTIC SURGERY.

The word "principle" which I have here employed is in common use in medicine. We speak of the principles of surgery, of medicine, of treatment, of pathology. In the sense in which it is thus employed the word means the essentialness, essential part of, important part, quintessence, pith, backbone, marrow, heart, and soul of these subjects. It includes not only the *facts*, but also some reference to the *reasoning*-grounds, way of thinking, reflection, conclusion, judgment, motive, springs of action that determine the action we take upon these facts.

If any of you, even the youngest, were asked by a layman what the "principles" of antiseptic surgery were he would probably not be able to give the whole facts and the whole chain of reasoning, observation, and experience on which the practice of antiseptic surgery is based. Even with the limited experience he possesses he would, if he were a wise student, be more likely to reply that the chief principle of antiseptic surgery is, of course, that organisms cause fever, inflammation, suppuration, etc., and hence the necessity for all the surgical precautions and the elaborate surgical ritual witnessed from day to day in surgical practice.

The motives and the grounds for antiseptic surgery are very clear and obvious, and are demonstrated daily in his surgical work. They are thrust upon his notice every moment of his surgical life; they are driven into him by the whole teaching and surroundings of his surgical work. He lives in a very atmosphere of worship of antiseptis; he conducts services at her shrine; he places offerings of clean hands and a pure antiseptic conscience and behavior on her altars. Figuratively, if not actually, he sees in flaming characters written above the doors of her holy of holies, the operation theater, the words, "Abandon Sepsis, all ye who enter here." And even if this escapes his notice, the janitor who guards the door is there to remind you, "Put on thy shoes, for the place on which thou enterest is antiseptic ground."

Is this ritual connected with surgical antiseptis overdone? Are its surroundings too ornate, its practice too ceremonial, its services too elaborate, its vestments and miters too striking? I think not, if the surgeon or doctor carries these antiseptic principles into practice wherever he meets with sepsis. On the contrary, they are educational to a degree. No shrine in connection with modern scientific medicine and practice appeals more to the imagination than that constituted by a modern operating theater. In no department of the whole field of modern medicine are its services to humanity so faithfully, so loyally, so scrupulously and exactly rendered as in that spot dedicated to antiseptic surgery.

pulously and exactly rendered as in that spot dedicated to antiseptic surgery.

What is the object of this whole elaborate ritual of observant practice? It is designed primarily for one great purpose, to prevent the access of organisms into the wounds which the surgeon has necessarily to make in the course of his surgical work. To avoid such an occurrence, such a catastrophe, as he would deem it, the surgeon takes every possible precaution that knowledge and experience suggest to him. No precaution is too minute, no duty, however trivial, appears to him as such in the attainment of his great object. He renders these services, he observes these precautions as faithfully and as strictly in the case of the outcast admitted from the poorest slum as he would to the highest personage in the land.

In the early days of antiseptic surgery the ritual was different, for the principles underlying it were also different. It was at first sight thought that organisms of any kind might produce the untoward results which the surgeon feared—hence the first observances of antiseptic surgery, the use of spraying during the operation and the elaborate and repeated dressings necessitated during the subsequent healing of the wound.

It is now known that the organisms which the surgeon has most to fear are not those in the air, but those present (staphylococci and streptococci) on the patient's skin, or on his own fingers, or on the instruments which he employs. His procedure is therefore now directed primarily, not against the organisms of the air, although precautions against these are involved in the arrangements he makes for the ventilation of his operating theater; nor yet primarily against the introduction of organisms from the walls and floors, although that source is also scrupulously kept in view in the plans he accepts for his floors and ceilings and walls, and in the ritual he observes in his work.

The full force of his precautions is directed against the introduction of septic organisms into his wound conveyed by his own fingers or those of his assis-

tants, or by his instruments. If he has an untoward result where he confidently expected a successful one, if fever occurs or his wound suppurates without obvious cause, his suspicions, if he is a good surgeon, would probably fall first upon his own fingers, secondly upon those of his assistants, thirdly upon his instruments, and fourthly, or lastly, upon the air in the theater. If he were a bad surgeon the order of suspicion would be reversed.

You will note that the whole procedure of the antiseptic surgeon is directed against the introduction of organisms into the body as the result of his own operation, or at least against their conveyance from places where they are already present—*e.g.* the intestine—into cavities such as the peritoneum, where their effects might be serious or fatal. His responsibility, in short, so far as preventing the access of organisms into the body, begins and ends there. If they gain access through his wounds, through the failure of any precautions on his part, he is responsible, and no one feels this responsibility more than he does. If, however, the organisms are already in the body, as they frequently are in abscesses and suppurations connected with the bones, joints, stomach, intestines, liver, kidney, and other organs which he is called on to relieve by operation, he is only responsible for seeing that, so far as he can help, the organisms shall not be conveyed by his procedure into adjacent parts. He is not—he considers—responsible for their original access to the parts where they are causing trouble. That is a *medical* or *pathological* matter with which he is not primarily concerned, and with which he cannot deal. And yet unknown to him, and unnoted by him, he may be allowing his patient to retain a degree of sepsis (in the mouth) which would receive his immediate attention were it found anywhere else. (See Cases 1-6, *infra*.)

SEPSIS IN MEDICINE.

I have dwelt upon this point, the extreme ritualistic regard which the surgeon shows toward sepsis in surgery, for

I wish to contrast it with the attitude of the medical profession toward the same (staphylococcal and streptococcal) sepsis in medicine—*i.e.* in medical diseases.

That attitude is a very curious one, as will presently appear. If a doctor were asked what it was, he would probably say that it differed in no way from that shown toward it in surgery. He was as keen to discover and remove sepsis and its various suppurative and necrotic effects in the domain of medicine—*e.g.* in connection with the throat, pharynx, stomach, duodenum, gall-bladder, liver, cecum, appendix, colon, or rectum, pelvis of kidney, the brain, the pleura and the lungs, the glands, etc.: or failing the presence of actual pus he was as keen and observant about the presence or absence of streptococci in the blood in cases of obscure blood poisonings, septicemias, ulcerative endocarditis, etc., as the surgeon was in the surgical domain. He could even point out that so much was this the case that these various regions of the body had been largely divided up among specialists, who devoted the greater part of their time to dealing with the various affections of these parts, among these affections septic infection being one of the commonest and most important. In short, his attitude toward sepsis in medicine, he would maintain, was precisely the same observant one as he was taught to show toward it in surgery. The only difference between the two cases, he might point out, was the unfortunate one that the sepsis he found in medicine was not so easily got at or so easily removable as it happily was in the domain of external surgery. But, as we saw, the regard which the surgeon shows toward sepsis in the domain of surgery is not confined to its removal when present. It has another and far greater object, namely, its prevention. It is not so much in the removal as in the prevention of sepsis that surgical antisepsis has won its great triumphs.

APPARENT RÔLE.

If the doctor were asked how the matter stood with regard to the *prevention*

of *medical sepsis*, he would probably say that that was a matter he unfortunately could not control. These septic suppurations unfortunately occurred in medicine as complications of various medical diseases; in fact, they were often the essential features of these diseases, or actually constituted them—perforations, appendicitis, empyema, liver abscess, cholecystitis, glandular abscesses, septicaemia, ulcerative endocarditis, etc. The occurrence of these grave septic conditions, whether local or general, depended upon the state of health of the parts affected or of the body as a whole; and the factors concerned in giving rise to them were therefore as many and as various as the many and various local or general factors affecting the health of the particular organ, or of the body as a whole. Staphylococcal and streptococcal organisms were always in the body, *e.g.* in the intestinal canal. It was unfortunately impossible to prevent them getting access now and again into other organs or into the blood. In any case, however common the above-named septic conditions might be, they were, after all, rare in comparison with the medical diseases with which he had to deal, of which they were only occasional complications or sequelæ. When they did occur they were matters for the surgeon, not for him. He found sufficient scope for his own work among the more purely medical complaints and illnesses of his patients, the various conditions of general ill-health presented by his patients—*i.e.* the malnutrition, the tonsillitic, nasopharyngeal, and glandular troubles of younger children; the dyspepsias, indigestions, gastric and duodenal ulcers, intestinal catarrhs and ulcerations, and liver disturbances of his older patients; their subacute and chronic rheumatic troubles; the simpler anemias of young girls, which usually yielded easily to treatment, although they, too, sometimes were curiously resistant to treatment; the much more severe and troublesome anemias of the middle and older periods of life; the multitude of their nervous complaints; their fevers of known nature (influenza or scarlet fever, diph-

theria, typhoid, measles, etc.), and their complications; still more, the fevers of unknown or obscure nature which they occasionally suffered from, and which were so troublesome both in diagnosis and in treatment.

These and other affections of a like kind were numerous and troublesome enough to occupy all his time and call for all his powers of diagnosis and all his skill in treatment by appropriate medicinal and dietetic measures. They took in the medical sphere the place and importance that sepsis and its prevention took in the surgical.

Complications of a septic nature sometimes occurred in connection with some of them. These called for the help of the surgeon. To the surgeon septic infection was an all-important factor of disease. The doctor, worried to death with the multitudinous complaints of his patients and the apparently multitudinous and obscure causes underlying them, might often feel envious—if he cared to be so—of the surgeon's easier task in having to deal so much and so successfully with the removal or prevention of one well-defined infection, septic infection. If only he were able to prevent the causes of his patient's troubles as quickly and as effectively as the surgeon prevents or gets rid of sepsis, his work in medicine, he might well say, would be a simpler and more interesting work both to his patients and to himself than it now is. Alas, however, from the point of view of prevention the medical diseases with which he had to deal arose from many causes connected with the habits of life and surroundings of the patients, difficult to ascertain, and when ascertained not so easily preventable or removable as the great factor of septic infection in surgery.

Sepsis in surgery, its action, prevention, or removal, was the greatest "principle" of pathology and practice with which the surgeon had to deal. Sepsis in medicine was a causal factor of altogether subsidiary importance; it was only one of many others. Even when it was present it was in most cases, if not in all, only a complication of other

diseases, not its primary cause. It was an accident, a "terminal complication" of some other and more important disease.

ACTUAL RÔLE.

Now, it is with this whole conception of the sphere of activity and importance of sepsis in medicine that my whole work for many years joins issue. What I wish to say to you today is that the above conclusions regarding its importance do not in my experience represent even approximately the actual pathological and clinical facts of the case.

In my clinical experience septic infection is without exception the most prevalent infection operating in medicine, and a most important and prevalent cause and complication of many medical diseases. Its ill effects are widespread, and extend to all systems of the body. The relations between these effects and the sepsis that causes them are constantly overlooked, because the existence of the sepsis is itself overlooked. For the chief seat of that sepsis is the mouth, and the sepsis itself, when noted, is erroneously regarded as the resultant of various conditions of ill health with which it is associated—not, as it really is, an important cause or complication.

The causal connection between the two sets of processes—the sepsis and its ill effects—can be demonstrated by the simple expedient of removing the sepsis and noting the striking effect which the removal has upon the existence, character, and intensity of the ill effects. The ill effects referred to include in individual cases every one of the diseases described in the foregoing section, and regarded as essentially medical in their character, viz, the general ill health, dirty, sallow complexion, the indigestions, the gastric and intestinal troubles, the anemias which resist treatment, the tonsillitis, pharyngeal, and glandular troubles of children, the chronic rheumatisms, obscure fevers and blood poisonings, etc.

The effects are not the same in all cases, any more than are the effects of septic infection in surgery or those of

tuberculous infection in medicine. They affect sometimes one system and sometimes another, in different degrees according to the individual susceptibility, just as a chronic tuberculous infection may in one case affect the glands of the neck, in another the joints, in another the bone, in another the lung, in another the meninges, in another the peritoneum, while in another it may affect them all.

So with this septic infection in medicine, the effects fall sometimes more on the tonsils, pharynx, or glands of the neck; sometimes more on the stomach, intestine, and colon; sometimes more on the blood, causing anemia, purpuras, chronic septicemia, obscure fever; sometimes more on the joints, causing so-called rheumatic trouble; sometimes more on the nervous system, or on the kidneys, and sometimes it falls in a fulminating way upon the blood as a whole, causing a general infection with streptococci with or without infective endocarditis.

The sum-total of ill effects which it produces—of the ill health and the incapacity occasioned by its presence—is very great. It is greater in my observation than that produced by any other single factor in medicine, or by any other single infection operating in general medicine.

Sepsis in medicine therefore ranks, in my experience, as the most prevalent and potent infective disease in the body. It therefore deserves the particular attention of the whole profession as much as it has hitherto received their particular neglect. It requires this attention at the hands of every branch of the profession. But it concerns especially the medical profession, the doctor whom the patient first consults. The responsibility for first detecting its existence, or realizing its significance as a potential cause or complication of the patient's disease, or of applying the first measures of treatment, all devolve upon him. It is his opinion and interpretation that will determine the degree of importance which the patient will attach to his condition. If he belittles what he sees, or, what is even more common, if he fails to observe

by close examination what lies before his eyes, the patient will not receive the advice or treatment he needs, and he will not allow others to give it to him.

"ORAL SEPSIS."

In the foregoing sketch of the chief spheres of the doctor's work and interest I omitted any reference to one other portion of the body which constantly comes under his observation, indeed, more often than any other; I mean the mouth. This omission was intentional on my part. The cases presently to be described, which could be multiplied by thousands and tens of thousands coming under the daily notice of doctors, illustrate how constant this omission is in practice.

There is no part of the body more commonly looked into by the doctor than the mouth. He looks at the tongue of every patient he sees, and learns much from its condition. It is notoriously a very unruly member, in more ways than one. It constantly "gives away" its owner in the ordinary affairs of his life, and it does the same in the matter of his diseases, for it yields the doctor most instructive and important information regarding the bodily health—the condition of digestion and the general health.

When looking into the mouths of his patients the doctor has often occasion to note incidentally the presence of defective or decayed teeth, as a general accompaniment and apparently as a part result of the poor health, poor nutrition, or wasting diseases from which they suffer. These defects of the teeth are so common that he has ceased to worry about them. He has often asked his patients how they can expect their digestion to be good. What else but indigestion can they expect if they will not have their teeth "put in order" by the dentist, or get the dentist to supply new ones? How can they expect to masticate their food properly with such defective teeth? But, as he may sorrowfully add, patients are "hopeless" in this matter; they will not "attend to" their teeth; not only so, they are also actually "touchy" on the

subject. The patient is quite willing to describe and discuss with the doctor all his other troubles and complaints, to which, as he says, he is a "martyr"—his indigestions, headaches, liver troubles, his rheumatism, his gout, and his "neuritis." But the subject of his teeth is his own affair, one between himself and his dentist. And the doctor regards it as such. "It is a matter of teeth and dentistry," with which he cannot deal.

What I desire to impress upon you students, and all students entering the profession, and all those already engaged in the practice of the profession, is, that it is "not a matter of teeth and dentistry." It is an all-important matter of sepsis and antiseptics that concerns every branch of the medical profession, and concerns very closely the public health of the community. It is not a simple matter of "neglect of the teeth" by the patient, as is so commonly stated, but one of neglect of a great infection by the profession, a great infective disease for which the patient is not primarily responsible any more than he is responsible for the contraction of typhoid fever or tuberculosis. The condition referred to is that to which I have given the name of "oral sepsis."

The title oral sepsis was first introduced into medical literature in a paper entitled "Oral Sepsis as a Cause of Disease."* My object in seeking for a special name, and, after consideration, in creating this one, was to emphasize the great fact that it is not the absence of teeth but the presence of sepsis, that it is not dental defects but septic effects, that it is not defective mastication but the effective sepsis associated with such dental defects or often present in conditions of gingivitis apart from such defects that are responsible for the ill health associated with "bad" mouths.

The second object was to emphasize the importance of the infection caused by staphylococcal and streptococcal organisms, as distinguished from the purely saprophytic infections in which the mouth abounds; or the temporary

* *British Medical Journal*, July 1900.

presence of specific organisms, *e.g.* typhoid, tubercle, pneumonia, etc.

The subject of oral sepsis, as I designated and defined it, namely, the septic lesions of streptococcal and staphylococcal infection found in the mouth, belongs to no one department of medicine or surgery. It is common ground on which the general doctor, physician, or surgeon, the throat-nose-and-ear and the eye specialist, specialists in children's diseases, in stomach diseases, in blood diseases, in "rheumatic" diseases, in fevers, in skin diseases, in nervous and mental diseases, and lastly, the dental surgeon, all meet on terms of equal responsibility. In its earliest manifestations no special knowledge is required to deal with it: a sound grasp of the principles underlying antiseptics alone is required. Unfortunately for the patient, it is precisely this grasp which I grieve to say is wanting.

One would think poorly of a surgeon or doctor who declined to take the responsibility of treating a follicular (that is, a "septic") tonsillitis, but insisted on handing over the case to a throat specialist, or who allowed a patient to suck continuously a number of septic sores on his finger. I think no less poorly of any doctor or surgeon who declines to make himself responsible for the treatment of much of the oral sepsis presented by many of his cases—for this is what patients are constantly doing. Wherein consists the pathological difference between a follicular tonsillitis and a foul, septic suppurating condition of the gums, with deposition of calcareous "crusts and scabs" (so-called tartar), covering and hiding septic wounds and ulcers, loaded, as microscopic examination shows, with staphylococci and streptococci. None whatever, except that the latter is exceedingly common and the tonsillitis is comparatively rare. The pathological condition in both is the same, namely, sepsis. Moreover, it is a sepsis as easily recognized and much of it as easily removed in the case of the one as in that of the other, and the more urgently requiring to be removed, since it is more important as a potential dis-

case factor than any other source of sepsis in the body.

But, it is urged, the condition is so common that it is impossible either to prevent it or to deal with it successfully; further, the ill effects are few and rare compared with the wide prevalence of the condition. As I originally showed (1900), and my further experience of the last ten years, supported by that of many others, fully demonstrates, the ill effects are both common and grave; that they are not more common is due solely to the great resisting power possessed by the mucosa of the mouth and gums.

This matter of oral sepsis is, therefore, of urgent importance in relation to the whole multifarious and widespread group of affections—medical, surgical, and dental—caused by the actual presence or toxic action of pyogenic organisms (staphylococci and streptococci).

My clinical experience satisfies me that if oral sepsis (and naso-pharyngeal) could be successfully excluded, the other channels by which "medical sepsis" gains entrance into the body might almost be ignored. Sepsis as an important and prevalent cause of disease in medicine would almost cease to exist, instead of being, as in my judgment it is at the present time, a more important and prevalent cause of disease in the domain of medicine than it is in that of surgery. Time was when the positions were reversed, when sepsis was so prevalent in the surgical wards that it overflowed into the medical wards in the form of some of its effects—for example, amyloid disease of the kidney and liver and intestine. Now the relations are otherwise. In the form of the various affections above mentioned the greatest variety and most severe manifestations of sepsis and its effects are, in my experience, to be found in medical wards, whence they overflow (in the form of appendicular, gall-bladder, pleuritic, pyelitic inflammations and suppurations) into the surgical wards.

It is, of course, impossible to keep staphylococci and streptococci out of the mouth, just as it is impossible to prevent

occasional access of diphtheria, typhoid, pneumococcus, tubercle, and other infections. But that fact does not deter us from taking the most extensive sanitary and hygienic precautions to keep typhoid or tubercle infection out of the water or milk we drink or the air we breathe. I am satisfied that by suitable measures this far greater evil of oral sepsis could be largely prevented.

I submit, then, once more—as I did in the first communications (1900) and later papers (1903) bearing the title of "Oral Sepsis"—that in the interests of the many sufferers from the great group of medical affections which it produces, this condition of oral sepsis, the chief channel of access of all pyogenic affections, is urgently deserving of increased notice and attention. Knowing as we do the pathogenic qualities of staphylococci and streptococci, we have not the slightest excuse for allowing the mouth, so easily accessible to local measures, to remain the chief seat of its open wounds and a veritable hotbed for their development and propagation; on the contrary, it is a severe reflection on our profession if we allow it.

> Even if the teeth were not subject to a very marked septic infective process, that which we term caries and carionecrosis, and always remained intact except in so far as they were affected by the septic infection in the gums and in the periosteum of the sockets, the infective processes in the gums constitute very important septic wounds, and are a great source of sepsis to the body. As a matter of experience this is often the case. The teeth remain intact or at least free from obvious caries or carionecrosis, but the gums and periosteum of the sockets are the seat of numerous septic wounds. These effects are shown by septic suppuration, by deposit of tartar, sometimes in great masses, on the teeth, on the gum margin, and beneath the gum margin, by the formation of pockets (septic ulceration of periodontium—periosteitis), absorption of bone, and loosening of the teeth in their sockets.

All these conditions are very obvious

to the doctor if looked for and observed, and they are very septic and productive of some of the worst septic effects on the bodily health. But in many cases they need not be so obvious, for the septic infection may be confined almost exclusively to the periodontium (periosteum) of the sockets, and be evidenced only by ulceration of that membrane, pocket formation, loosening of the teeth, suppuration; sometimes, however, by very slight suppuration.

It is in poor patients that these septic conditions are most common. They have had "no care" of their mouths; their fate is the relatively happier one of having their septic roots lying exposed in all their nakedness surrounded with tartar, overgrown it may be by foul, septic, fungating gums. This sepsis is relatively open and above-board; it stares one in the face when it is looked for. At the worst it is covered by plates—which they have been told not to remove (!)—covering septic roots—which they have been told to keep (!) in order to prevent any falling-in of the gums. The conditions in these cases, atrociously septic as they are, are comparatively easily dealt with, for they can be seen and recognized, and even if the patient refuses to have his roots removed, much of the sepsis is superficial, and can be got at and removed by careful daily swabbing with antiseptic lotions. And if this can be done regularly the patient may ultimately be induced to have the septic root removed.

But the problem presented by similar conditions in private patients is a much more difficult one. One of the worst cases of sepsis I have ever seen was brought me by a doctor who told me that the mouth had been "carefully seen to and was in good order." The patient was a tall, handsome man in the prime of life, a case of severest Addisonian so-called "pernicious" idiopathic anemia. His mouth was, indeed, clean to all outside appearance, for it was one mass of gold caps, bridges, crowns, fillings, false teeth, etc., so ingeniously built up that one could hardly tell what was false and what was real. To free that man from

his sepsis in his state of health involved what was really equivalent to a major operation in surgery. The conditions of sepsis, necrosis, etc., revealed on removal of this golden architecture were perfectly appalling.

No one has probably had more reason than I have had to admire the sheer ingenuity and mechanical skill constantly displayed by the dental surgeon. And no one has had more reason to appreciate the ghastly tragedies of oral sepsis which his misplaced ingenuity so often carries in its train. Gold fillings, gold caps, gold bridges, gold crowns, fixed dentures, built in, on, and around diseased teeth, form a veritable mausoleum of gold over a mass of sepsis to which there is no parallel in the whole realm of medicine or surgery. The whole constitutes a perfect gold trap of sepsis of which the patient is proud, and which no persuasion will induce him to part with; for has it not cost him much money, and has he not been proud to have his black roots elegantly covered with beaten gold, although no ingenuity in the world can incorporate the gold edge of the cap or crown with the underlying surfaces of the root beneath the edges of the gums? There is no rank of society free from the fatal effects on health of this surgical malpractice.

(I speak from experience. The worst cases of anemia, gastritis, colitis of all kinds and degrees, of obscure fever of unknown origin, of purpura, of nervous disturbances of all kinds ranging from mental depression up to actual lesions of the cord, of chronic rheumatic affections, of kidney disease, are those which owe their origin to, or are gravely complicated by, the oral sepsis produced in private patients by these gold traps of sepsis. Time and again I have traced the very first onset of the whole trouble of which they complained to a period within a month or two of their insertion. The sepsis hereby produced is particularly severe and hurtful in its effects, for it is dammed-up in the bone and in the periosteum, and cannot be gotten rid of by any antiseptic measures which the patient or the doctor can carry out.

Moreover, it is painless, and its septic effects therefore go on steadily accumulating in intensity without drawing attention to their seat of origin.

Such are the fruits of this baneful so-called "conservative dentistry." The title would be a fitting one if the teeth were a series of ivory pegs planted in stone sockets. But the teeth being what they are, namely, highly developed pieces of bone tissue, possessing, I would point out, a richer blood- and nerve-supply than any piece of tissue of the same size in the whole body, and planted in sockets of bone with the closest vascular relations to the bone and the soft tissues of the periosteum and the gums, the title that would best describe the dentistry here referred to would be that of "septic dentistry." Conservative it is, but only in one sense. It conserves the sepsis which it produces by the gold work it places over and around the teeth, by the satisfaction which it gives the patient, by the pride which the dentist responsible for it feels in his "high-class American" work, and by his inability or unwillingness to recognize the septic effects which it produces.

After ten years' experience of the nature of these effects and of the difficulties encountered in removing them, I feel that the only solution of the difficulty may best be described in the terms employed by Huxley, modified to suit this particular case:

There can be no doubt that the future of oral pathology and treatment, and therefore of practical dentistry, depends upon the extent to which those who occupy themselves with these subjects are trained in the principles and impregnated with the fundamental truths of oral sepsis and oral antisepsis.

The problem is an important one for the dental profession, and its solution is an important one in the interests of public health, especially of our school children, thirty to fifty per cent. of whom suffer from dental and oral sepsis and its tonsillitic, pharyngeal, glandular, and other effects. For while a large body of that profession are engaged in dealing successfully with the difficult

problems of dental disease and of oral sepsis, another body is no less steadily engaged in promoting sepsis of the worst character and degree by ignoring the fundamental truths connected with the anatomy, physiology, and pathology of the tissues with which they deal. To gold-cap a healthy or a diseased tooth in order to beautify or "preserve" (!) it is the negation of every one of these truths—a veritable apotheosis of septic surgery, and of surgical and medical malpractice.

The medical ill effects of this septic surgery are to be seen every day in those who are the victims of this gilded dentistry—in their dirty-gray, sallow, pale, waxlike complexions, and in the chronic dyspepsias, intestinal disorders, ill health, anemias, and nervous ("neurotic") complaints from which they suffer. In no class of patients and in no country are these, in my observation, more common than among Americans and in America, the original home of this class of work.

CLINICAL EFFECTS OF SEPSIS.

The chief feature of this particular oral sepsis is that the whole of it is swallowed or absorbed into the lymphatics and blood. Unlike the sepsis of open wounds on the outside of the body, none of it is got rid of by free discharge on the surface. The effects of it, therefore, fall in the first place upon the whole of the alimentary tract from the tonsils downward. These effects include every degree and variety of tonsillitis and pharyngitis, of gastric trouble from functional dyspepsia up to gastritis and gastric ulcer, and every degree and variety of enteritis and colitis, and troubles in adjacent parts—*e.g.* appendicitis. The effects fall in the second place upon the glands (adenitis), on the blood (septic anemia, purpura, fever, septicemia), on the joints (arthritis), on the kidneys (nephritis), and on the nervous system.

I cannot within the time at my disposal bring before you all the facts relating to medical sepsis or to its greatest cause—oral sepsis—on which these

conclusions as to their importance are based. This I have done in the series of papers already referred to. I propose rather to deal with you as you dealt with your assumed inquirer in the matter of antiseptic surgery, namely, enunciate briefly certain definite principles that may appeal to you, and illustrate these by a few recent cases selected at random.

The first of these principles is that the sepsis here had in view is all swallowed or absorbed, and that infection with staphylococcal and streptococcal organisms carries with it certain definite and deleterious effects wherever it is found. These effects vary, naturally, with the site of the infection and the degree of resistance offered by the tissues which are the seat of the invasion.

In the case of the mouth the mere presence of staphylococci and streptococci on the surface of the mucosa, or on the tongue, or in the mouth secretions, or in the saprophytic flora which abounds in the mouth, does not of itself cause disease, any more than their presence on the uninjured skin. But the matter is totally different when they become seated in open wounds in the edges of the gums adjacent to carious teeth; or extend from this, their first site, downward along the periosteum (periodontal membrane) of the tooth socket. The infection is then no longer a superficial one, it is in connection with the soft tissues, periosteum, and bone. The resistance of these tissues, especially the gums, is fortunately very great, hence a degree of infection which anywhere else in the body would certainly draw attention to itself by its redness, swelling, heat, and pain, may indeed cause redness and swelling, but does not necessarily cause any pain. This is the more to be regretted in that a feature of septic infection in the gums, the teeth, or the sockets of the teeth, is that it is infection in contact with diseased bone, and its virulence is intensely aggravated by this fact. For no septic infection is more intensely virulent than that connected with diseased bone. I speak from personal experience on this point. The

only two occasions in which I ran a very close risk—in one instance of my life, in the other of a limb or my life—were two in which in my postmortem work I contracted a blood poisoning from pus arising in connection with diseased bone. One of these was of a case of "septic anemia," in which I pricked my finger while handling the tongue from a mouth full of oral sepsis. The symptoms showed themselves in twelve hours, and were ushered in by faintness and rigors, fever of 103° to 104° , and cellulitis of the whole arm before any local disturbance had shown itself.

Such untoward effects in the case of infection of the gums or jaws are very rare, although I have seen complete gangrenous necrosis of the whole of the alveolus and the bone of the hard palate, pyemia, and death to result from this infection. But although such fulminating effects are exceptional, septic effects of various kinds and degrees are invariably present. These effects are not proportionate to the mere amount of the existing sepsis, but depend on its virulence. The most intense anemia, blood poisoning, hectic fever, and even ulcerative endocarditis may in my experience be produced by one septic amalgam filling, or by a small deep-seated alveolar abscess, or an unrecognized suppuration of the antrum or nasal sinuses. On the other hand, a man may have the foulest sepsis for years without apparently any ill effect. But he need not vaunt himself unduly upon this comparative immunity; sooner or later his sepsis will find him out (see case 10). For even if it does not itself produce definite disease of its own, it will certainly complicate any independent disease from which he may afterward suffer, and its effects, although unrecognized, may really constitute some of the most prominent features of his disease (cases 7, 8, 9, and 10).

A patient's illness is not necessarily made up of the effects of his chief disease. The degree of ill health or of the gastric, intestinal, febrile, anemic, and nervous disturbances from which he suffers are by no means necessarily con-

nected with, and due to, his chief disease. The chief interest of clinical as distinguished from systemic medicine, lies in the recognition of this great fact—in, so to speak, dissecting out all the causal factors operating in any individual case, and in removing so far as possible every adventitious factor, even if the chief one, *e.g.* permanent organic disease, is beyond control.

CASES.

CASE 1. *Septic gastritis.* A patient, a man, age thirty-two, was admitted suffering from chronic indigestion and gastric trouble. His habits had been regular, his bodily physique was good. There was no apparent reason why he of all men should be subject to gastric trouble. On examination I found he had a tooth-plate in his upper jaw which he had not removed for two and a half years (having been told not to do so), and which, even now, he could only remove with difficulty and after persuasion. On its removal there was found the most intense septic inflammation and ulceration of the gums around a number of necrosed roots underneath the plate. This was immediately dressed by me. After careful antiseptic dressing for several days to get rid of some of the septic infection, with immediate and obvious benefit to the patient, he ultimately consented to have the roots removed, and the patient left the hospital in a week or two entirely free from all gastric trouble. The condition was septic gastritis produced by an intense oral sepsis, due to the insensate action of a dentist in supplying and fixing a plate to be worn over necrosed roots.

Nine-tenths of the cases of dyspepsia and gastric trouble which I see are caused or complicated by similar oral sepsis, and respond at once to removal of this sepsis. Nevertheless the sepsis is overlooked because not looked for.

CASE 2. *Septic gastritis.* I was shown recently a very severe and obscure case of gastritis in a woman of thirty-three. She presented a dirty gray complexion and a broken-down appearance. The fullest report of her case was read to me, including the results of a chemical and microscopical examination of her stomach contents and of her feces. On examination she presented the most intense oral sepsis, ulceration of

the gums, with large deposits of tartar covering the ulcers and extending up to, and inclosing, the teeth, many of these being quite loose in their sockets. She had swallowed this infection for years, and it had caused not only "septic" gastritis, but also septic colitis, for, as was duly noted, pus was present in the feces.

Everything in connection with the case had been duly observed and recorded, including the presence of pus in the feces. But the condition of the mouth, although noted to be bad, had not been dealt with.

CASE 3. "*Septic colitis.*" A patient was admitted suffering from chronic colitis of many years' standing; he had been an in-patient of other hospitals for the same complaint. He passed large masses of mucus with each motion. The case was so-called "mucous colitis," a title which seems to mean something definite, but merely means that he has some kind of colitis, and that he is passing mucus. On examination I found he had some twenty rotten roots in his mouth, all of them necrosed down to the level of the gum. The infection had all been swallowed for many years. I termed the condition *septic colitis*. The teeth were carefully dressed for several days and then extracted. Three or four days later the patient ceased to pass any more clumps of mucus in his stools, the bowels became regular, and in two or three weeks' time he went out free from all intestinal trouble. The condition was one of septic colitis caused by oral sepsis.
